About this information

These topics provide reference information for IMS™ system application programming interface (API) calls for IMS Common Queue Server (CQS); IMS Common Service Layer (CSL); IMS data propagation with IMS DataPropagator for z/OS®; IMS Database Resource Adapter (DRA); IMS Database Recovery Control (DBRC) facility; IMS Repository Server (FRPBATCH); and VTAM® and SNA.

This information is available in IBM® Knowledge Center.

Prerequisite knowledge

Before using this information, you should have knowledge of either IMS Database Manager (DB) or IMS Transaction Manager (TM). You should also understand basic z/OS and IMS concepts, your installation’s IMS system, and have general knowledge of the tasks involved in project planning.

You can learn more about z/OS by visiting the “z/OS basic skills” topics in IBM Knowledge Center.

You can gain an understanding of basic IMS concepts by reading An Introduction to IMS, an IBM Press publication.

IBM offers a wide variety of classroom and self-study courses to help you learn IMS. For a complete list of courses available, go to the Resources section of the IMS home page at ibm.com/ims and link to the Training and Certification page.

IMS function names used in this information

In this information, the term HALDB Online Reorganization refers to the integrated HALDB Online Reorganization function that is part of IMS Version 13, unless otherwise indicated.

How new and changed information is identified

New and changed information in most IMS library PDF publications is denoted by a character (revision marker) in the left margin. The first edition (-00) of Release Planning, as well as the Program Directory and Licensed Program Specifications, do not include revision markers.

Revision markers follow these general conventions:

- Only technical changes are marked; style and grammatical changes are not marked.
- If part of an element, such as a paragraph, syntax diagram, list item, task step, or figure is changed, the entire element is marked with revision markers, even though only part of the element might have changed.
- If a topic is changed by more than 50%, the entire topic is marked with revision markers (so it might seem to be a new topic, even though it is not).

Revision markers do not necessarily indicate all the changes made to the information because deleted text and graphics cannot be marked with revision markers.
How to read syntax diagrams

The following rules apply to the syntax diagrams that are used in this information:

- Read the syntax diagrams from left to right, from top to bottom, following the path of the line. The following conventions are used:
  - The >>>-- symbol indicates the beginning of a syntax diagram.
  - The ---> symbol indicates that the syntax diagram is continued on the next line.
  - The >--- symbol indicates that a syntax diagram is continued from the previous line.
  - The -->< symbol indicates the end of a syntax diagram.
- Required items appear on the horizontal line (the main path).

```
>>>required_item--
```

- Optional items appear below the main path.

```
>>>required_item<---optional_item
```

If an optional item appears above the main path, that item has no effect on the execution of the syntax element and is used only for readability.

```
>>>required_item<---optional_item
```

- If you can choose from two or more items, they appear vertically, in a stack. If you must choose one of the items, one item of the stack appears on the main path.

```
>>>required_item<---required_choice1
          <---required_choice2
```

If choosing one of the items is optional, the entire stack appears below the main path.

```
>>>required_item<---optional_choice1
          <---optional_choice2
```

If one of the items is the default, it appears above the main path, and the remaining choices are shown below.

```
>>>required_item<---default_choice
          <---optional_choice
          <---optional_choice
```

- An arrow returning to the left, above the main line, indicates an item that can be repeated.
If the repeat arrow contains a comma, you must separate repeated items with a comma.

A repeat arrow above a stack indicates that you can repeat the items in the stack.

- Sometimes a diagram must be split into fragments. The syntax fragment is shown separately from the main syntax diagram, but the contents of the fragment should be read as if they are on the main path of the diagram.

- In IMS, a b symbol indicates one blank position.
- Keywords, and their minimum abbreviations if applicable, appear in uppercase. They must be spelled exactly as shown. Variables appear in all lowercase italic letters (for example, column-name). They represent user-supplied names or values.
- Separate keywords and parameters by at least one space if no intervening punctuation is shown in the diagram.
- Enter punctuation marks, parentheses, arithmetic operators, and other symbols, exactly as shown in the diagram.
- Footnotes are shown by a number in parentheses, for example (1).

**Accessibility features for IMS Version 13**

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

**Accessibility features**

The following list includes the major accessibility features in z/OS products, including IMS Version 13. These features support:

- Keyboard-only operation.
- Interfaces that are commonly used by screen readers and screen magnifiers.
- Customization of display attributes such as color, contrast, and font size.

**Keyboard navigation**

You can access IMS Version 13 ISPF panel functions by using a keyboard or keyboard shortcut keys.
For information about navigating the IMS Version 13 ISPF panels using TSO/E or ISPF, refer to the z/OS TSO/E Primer, the z/OS TSO/E User’s Guide, and the z/OS ISPF User’s Guide Volume 1. These guides describe how to navigate each interface, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

**Related accessibility information**

Online documentation for IMS Version 13 is available in IBM Knowledge Center.

**IBM and accessibility**

See the IBM Human Ability and Accessibility Center at [www.ibm.com/able](http://www.ibm.com/able) for more information about the commitment that IBM has to accessibility.

**How to send your comments**

Your feedback is important in helping us provide the most accurate and highest quality information. If you have any comments about this or any other IMS information, you can take one of the following actions:

- Click the **Feedback** link at the bottom of any [IBM Knowledge Center](http://www.ibm.com/able) topic.
- Send an email to imspubs@us.ibm.com. Be sure to include the book title and the publication number.
Part 1. Common Queue Server (CQS)

You can use this information to learn about writing a CQS client and CQS client requests.
Chapter 1. Writing a CQS client

Your CQS client communicates with CQS through requests. You must write one or more CQS clients in order to use CQS to manage resource and queue structures for your product or service.

There are various considerations that you must take into account when writing a Common Queue Server (CQS) client. The information in these topics is written primarily for the programmer who writes the client, but also for CQS administrators or system programmers who must become aware of some of the issues involved in designing and writing a CQS client.

This topic contains General-use Programming Interface information.

Related concepts:
- Chapter 2, “CQS client requests,” on page 15

Summary of CQS client requests

CQS client requests enable a client to access CQS or shared queues on coupling facility list structures. Your primary tool for writing a CQS client is the set of client request macros that CQS provides. You can use these requests to enable a client to access CQS or the shared queues on coupling facility list structures.

The following list summarizes the CQS requests:

- **CQSBRWSE**: Retrieves a copy of a data object from a queue
- **CQSCHKPT**: Takes a checkpoint of internal tables or of all data objects on a structure
- **CQSCONN**: Connects a client to one or more structures
- **CQSDEL**: Deletes one or more data objects from a queue
- **CQSDEREG**: De-register a client from its CQS, terminating communication with it
- **CQSDISC**: Disconnects a client from one or more structures
- **CQSINFRM**: Registers client interest in one or more queues, notifying the client when work exists on the queue
- **CQSMOVE**: Moves one or more data objects from one queue to another
- **CQSPUT**: Places a data object on a queue
- **CQSQUERY**: Requests information about a queue or a structure
- **CQSREAD**: Retrieves and locks a copy of a data object from a queue
CQSRECVR
Recover data objects that were moved to the cold queue after a client or CQS cold starts

CQSREG
Registers a client with a CQS, establishing communication

CQSRSYNC
Resynchronizes in-doubt data between the client and its CQS after a failure

CQSSHUT
Shuts down a CQS

CQSUNLCK
Unlocks a data object, making it available to any client

CQSUPD
Updates one or more uniquely named resources on a resource structure

Sequence of CQS requests issued by a client for queue structure

A client uses CQS requests to make use of CQS services and resources. Client requests for CQS services must be in a particular sequence, which is outlined in this table.

The client must issue certain requests to request CQS services, and some of the requests must be in a particular sequence; the sequence for CQS requests is shown in the following table. Other requests can be issued multiple times, in any order, based on the processing requirements of the client.

Table 1. Sequence for CQS requests

<table>
<thead>
<tr>
<th>Order</th>
<th>Request</th>
<th>Use for request</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>CQSREG</td>
<td>To establish communications with CQS.</td>
</tr>
<tr>
<td>2</td>
<td>CQSCONN</td>
<td>To connect to a particular structure.</td>
</tr>
<tr>
<td>3</td>
<td>CQSRSYNC</td>
<td>To resolve indoubt work with CQS.</td>
</tr>
<tr>
<td>4</td>
<td>CQSRECVR</td>
<td>After a CQS cold start to recover specific data objects.</td>
</tr>
<tr>
<td>5</td>
<td>CQSINFRM</td>
<td>To register interest in specific queue names.</td>
</tr>
<tr>
<td>6</td>
<td>Other CQS requests</td>
<td>To process work. Examples of these other requests are CQSBRWSE, CQSPUT, and CQSREAD.</td>
</tr>
<tr>
<td>7</td>
<td>CQSDISC</td>
<td>To disconnect from a structure.</td>
</tr>
<tr>
<td>8</td>
<td>CQSSHUT</td>
<td>To request CQS to shutdown. The client could also use CQSDISC ... CQSSHUT=YES to disconnect from a structure and request a CQS shutdown, rather than issuing only the CQSSHUT request.</td>
</tr>
<tr>
<td>9</td>
<td>CQSDEREG</td>
<td>To end communications with CQS.</td>
</tr>
</tbody>
</table>

Note:
1. A client can issue the CQSRECVR and CQSINFRM requests in any order and at any time following the CQSRSYNC request. The client should, however, issue both of these requests before starting any real work with CQS.
Considerations for coding CQS requests

Various keywords, parameters, and variables are available for use with CQS requests. The interface that you select for the client's state determines the allowed environment for all subsequent CQS requests and all client exit routines driven by CQS.

The usage topic for each request describes the detail for each of the keywords, parameters, and variables for the CQS requests, but a few global usage considerations apply to all of the requests.

Authorization for CQS

CQS provides two interfaces for its clients: the authorized interface and the non-authorized interface. CQS automatically selects and initializes the correct interface environment based on the client's state when the client issues a CQSREG request. If the client is authorized (in supervisor state with PSW key 0 to 7), CQS initializes the authorized interface environment. If the client is not authorized (in problem state with key 8 or greater), CQS initializes the non-authorized interface environment.

Which interface CQS assigns to the client determines the allowed environments for all subsequent CQS requests and all client exit routines driven by CQS. In general, when a client makes a CQS request, its PSW state and key must be the same as they were when it issued the CQSREG request.

How CQS requests use registers

All CQS requests use registers R0, R1, R14, and R15 as work registers. When a CQS request returns control to the caller, the contents of these registers are not the same as they were before the macro call. R15 contains a return code, and R0 contains a reason code from the CQS interface. The contents of registers R2 through R13 remain unchanged after a CQS request, except for registers specified as output parameters for the particular request.

All CQS requests require register R13 to point to a standard 72-byte save area. No other registers are required to contain any particular value when a CQS request is issued, except for registers specified as input parameters for the particular request.

Coding parameters for CQS requests

For all of the parameters (shown in the syntax diagrams as, for example, parameter) that are not literals, CQS expects either an address or a value. For example, for the cqstoken on a CQSREAD request, CQS expects the address of the 16-byte CQS token, but for the buffersize, CQS expects a 4-byte buffer size.

To pass an address or a parameter value to CQS, you can code the parameter for the CQS request in one of three ways:

1. Use a register
   To use a register, you must load the address or the parameter value into one of the general purpose registers, then use that register (enclosed in parentheses) for the parameter in the CQS request.
LA 5, TOKEN
CQSREAD FUNC=READ,CQSTOKEN=(5), ...

::
TOKEN DS XL16

**Figure 2. Passing a value for register**

L 4, MYBUFLEN
CQSREAD FUNC=READ,BUFSIZE=(4), ...

::
MYBUFLEN DC F'00000024'

2. Use a symbol
To use a symbol name, you must define a symbol that contains the address or the parameter value, then use that symbol for the parameter in the CQS request.

**Figure 3. Passing an address for symbol**

CQSREAD FUNC=READ,CQSTOKEN=TOKENADR,...

::
TOKENADR DC A(TOKEN) TOKEN DS XL16

**Figure 4. Passing a value for symbol**

CQSREAD FUNC=READ,BUFSIZE=MYBUFLEN,...

::
MYBUFLEN DC F'00000024'

3. Use a symbol value
To use a symbol value, you must define a symbol or an equate that contains the parameter value, then use that symbol (preceded by the at-sign, @, and enclosed in parentheses) for the parameter in the CQS request.

**Figure 5. Passing a value for symbol value**

CQSREAD FUNC=READ,CQSTOKEN=@(TOKEN), ...

::
TOKEN DC XL16 '0000A765B55CFF00'

**Figure 6. Passing an equate for symbol value**

CQSREAD FUNC=READ,BUFSIZE=@(MYBUFLEN), ...

::
MYBUFLEN EQU 24
**Literals for CQS requests**

A number of CQS request macros have parameters that use a literal (for example, the LOCAL parameter on the CQSREAD request macro). A macro invocation can use either combinations of literal parameters or the OPTWORD1 parameter to pass 4 bytes containing flags that represent the literals. When you use the OPTWORD1 parameter, you obtain the literal equates by using the DSECT function of each request macro. The equates that represent the literal values are added together in a regular storage location.

**Requirement:** A macro invocation can use either the literal parameters or the OPTWORD1 parameter, not both. When a macro invocation includes the OPTWORD1 parameter, the value passed on this parameter must include one equate for each literal parameter supported by the macro. For example, the CQSREAD request has three literal parameters: LOCAL, PARTIAL, and QPOS. The value you pass on the OPTWORD1 parameter must include one equate for the LOCAL parameter, one equate for the PARTIAL parameter, and one equate for the QPOS parameter.

To code a CQSREAD request using a series of literal parameters, use CQSREAD FUNC=READ,...,QPOS=FIRST,LOCAL=YES....

**Coding CQSREAD with the OPTWORD1 parameter**

To code the same CQSREAD request using the OPTWORD1 parameter, use the example shown in the following example.

```plaintext
L R2,=A(CQSREAD_QPOSF+CQSREAD_LCLY+CQSREAD_PRTLY)
CQSREAD FUNC=READ,...,OPTWORD1=(R2),...
```

**Event Control Blocks with CQS requests**

Some requests allow you to use a z/OS event control block (ECB). If you specify an ECB (ECB=ecbaddress), the client immediately receives control after issuing the request, but must at some time be sure to wait for the request to post the ECB. If you do not specify an ECB, CQS does not return control to the client until CQS completes its processing for the request.

**Lists in the CQS requests**

Some of the CQS requests have a LIST keyword, which specifies the address of a parameter list entry. This keyword specifies the address of the first list entry. If you want to pass multiple list entries, you must ensure that they all reside in contiguous storage, that is, the next entry must begin at the first byte following the current entry. All lists must be contiguous, even if they are not aligned on word or fullword boundaries.

**Assembling a program with CQS requests**

The CQS request macros are shipped with IMS and are included in the IMS.ADFSMAC data set. When you assemble a program that includes CQS request macros, you must tell the assembler to look for the macros in this data set. You can also copy the members from the IMS data set to another data set, as necessary.
There are no special requirements for link editing a program that includes CQS requests, but you do have to ensure that the IMS.SDFSRESL data set is concatenated with your JOB or STEPLIB DD statement for the client job.

**STEPLIB DD statement to concatenate IMS.SDFSRESL**

To concatenate the IMS.SDFSRESL data set after your MYPROGS.SDFSRESL data set, code your STEPLIB DD statement as shown in the following example.

```
STEPLIB DD DSN=MYPROGS.SDFSRESL,DISP=SHR
          DSN=IMS.SDFSRESL,DISP=SHR
```

**Related concepts:** [Chapter 2, “CQS client requests,” on page 15](#)

**Related reference:** [z/OS: Initializing extended ECBs and ECB extensions](#)

**Environmental requirements for CQS**

Environmental requirements depend on the CQS interface assigned to the client for CQS requests other than CQSREG and CQSDEREG requests.

The following table shows the environment for clients using the authorized CQS interface:

<table>
<thead>
<tr>
<th>Environment aspect</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>Supervisor state and PSW key 0-7 (PSW key must match the PSW key when the CQSREG request was issued)</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any, however, PASN must equal the primary address space in which the CQSREG request was issued</td>
</tr>
<tr>
<td>AMODE</td>
<td>31</td>
</tr>
<tr>
<td>ASC Mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Home address space</td>
<td>Any</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>

</tbody>
</table>

The following table shows the environment for clients using the non-authorized CQS interface:

<table>
<thead>
<tr>
<th>Environment aspect</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>Problem state or PSW key 8 (PSW key must match the PSW key when the CQSREG request was issued)</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>None (PASN=SASN=HASN)</td>
</tr>
</tbody>
</table>
Table 3. Environment for CQS requests (excluding CQSREG and CQSDEREG) using the non-authorized interface (continued)

<table>
<thead>
<tr>
<th>Environment aspect</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>AMODE</td>
<td>31</td>
</tr>
<tr>
<td>ASC Mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Home address space</td>
<td>Address space in which CQSREG was issued</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for interrupts</td>
</tr>
<tr>
<td>Control parameters</td>
<td>In primary address space</td>
</tr>
</tbody>
</table>

The environmental requirements for the CQS register and deregister requests (CQSREG and CQSDEREG) are different from all of the other CQS requests. Authorized clients must issue CQSREG and CQSDEREG requests in the environment shown in the following table.

Table 4. Environment for CQSREG and CQSDEREG requests using the authorized interface

<table>
<thead>
<tr>

Return codes and reason codes for CQS requests

CQS return and reason codes indicate the success or failure of sending the request to the CQS address space and reflect the success or failure of the particular CQS request that is being made.
With the exception of CQSREG and CQSDEREG, each CQS request returns two sets of return and reason codes. One set is returned by the CQS interface, and indicates the success or failure of sending the request to the CQS address space (these are returned in R15 and R0). The other set is returned by the CQS address space, and reflects the success or failure of the particular CQS request being made (these are returned in the fields indicated by the RETCODE and RSNCODE parameters on the CQS request macro).

When you make a CQS request, the request must travel through the CQS interface from the client address space to the CQS address space. The CQS interface returns information about the success or failure of the sending of the request in registers R15 and R0. After issuing a CQS request macro, have your code check the value in R15 first. If the value in R15 is zero, then the CQS interface successfully sent the request to the CQS address space. If R15 is not zero, the CQS interface was unable to send the request to the CQS address space, and R0 contains a reason code that explains the error.

The return and reason codes from the CQS request itself are returned in the fields specified with the RETCODE and RSNCODE parameters coded on the CQS request macro. The values returned in these fields are valid only if the CQS interface return code (R15) is zero. If the interface return code in R15 is not zero after you issue a CQS request macro, then the values in the RETCODE and RSNCODE fields are not predictable, and you should not use them.

For synchronous requests (that is, requests in which the ECB parameter was not coded), the RETCODE and RSNCODE fields are set after your module receives control back from the request macro, and you can use them immediately. For asynchronous requests (that is, requests in which the ECB parameter was coded), the RETCODE and RSNCODE fields are set only after the ECB is posted by CQS. Do not check the RETCODE and RSNCODE fields until you have issued a WAIT on the ECB you specified on the request, and that WAIT has returned.

The CQSREG and CQSDEREG requests are exceptions to this. CQSREG and CQSDEREG register and deregister a client with the CQS interface, but do not actually send a request across the interface to the CQS address space. CQSREG and CQSDEREG have only a single set of return and reason codes, and these are immediately available upon return from the register or deregister request. The return code is set both in register 15 and in the field specified by RETCODE on the request macro. The reason code is set both in register 0 and in the field specified by RSNCODE on the request macro.

The CQS interface issues the return and reason codes shown in the following table. Any CQS request can receive these return and reason codes. Because the CQS interface performs more extensive checking for non-authorized clients, some of the following return and reason codes can only be received if the client is a non-authorized client.

<td>X'00000644'</td>
<td>The CQS request abended while CQS was copying the request parameters. This error is usually caused by the client's passing bad parameter data.</td>
</tr>
<tr>
<td>X'00000014'</td>
<td>X'00000648'</td>
<td>The interface parameter list version passed by the CQS request macro was not valid. This error is probably caused by a difference in versions between the CQS client and the CQS address space the client is trying to use.</td>
</tr>
</tbody>
</table>

All CQS requests have a DSECT function that you can use to include equate statements in your program for all the return and reason codes for the request.

**Recommendation:** Write a program that specifies FUNC=DSECT for all CQS requests so you can determine symbolic variable names to use for the return and reason code values.
CQS clients and handling special events

A CQS client must be able to either initiate or participate in many different types of events. You must be aware of what the CQS client can do in these events in order to handle them appropriately.

A CQS client must be able either to initiate or to participate in many different types of events. This topic describes some of these special events and what the CQS client can or must do about them.

CQS cold start

When CQS cold starts after connecting to a structure that contains data, CQS looks for unresolved work from CQSMOVE or CQSDEL requests. CQS backs out CQSMOVE requests and completes CQSDEL requests. CQS then performs a system checkpoint, and restart is complete.

CQS does not resolve work that is initiated using a CQSREAD request. As a result, data objects might remain on the queues. The client can issue the CQSRSYNC request to have CQS move these data objects to the cold queue and notify the client that they exist. The client can then issue a CQSRECVR request to access these data objects.

Recommendation: Complete all work initiated using CQSPUT requests because CQS is not aware of these data objects.

Registering interest in queues with CQSINFRM

Use the CQSINFRM request to allow CQS to notify the client when a data object exists on a queue or when the queue becomes non-empty. The client must register interest in a queue before it is notified of work on that queue.

Working with objects on the cold queue using CQS requests

CQS places objects on the cold queue when either CQS or the client is cold started while there are objects in active structures. A client can use the CQSBRWSReq request to examine objects on the cold queue, and then, using the cold-queue token and UOW returned by this request, the client can use a CQSRECVR request to retrieve or delete objects from the cold queue.

When writing a CQS client, you can use the following request to obtain information about objects on the cold queue, including the qnames, data object count, oldest data object time stamp, and newest data object time stamp:

CQSQUERY FUNC=QTYPE,QTYPENM=COLDQ

Initiating checkpoints using CQS requests

A CQS client can initiate a system checkpoint by issuing a CQSCHKPT FUNC=CHKPTSYS request. A CQS client can initiate a structure checkpoint by issuing a CQSCHKPT FUNC=CHKPTSTR request.

Shut down CQS

To shut down CQS, clients can either issue the CQSSHUT request or the CQSDISC request with CQSSHUT=YES specified. In either case, CQS terminates when there are no more structure connections. CQS continues to accept input and output.
requests so that in-progress work can complete. Structure checkpoints are allowed to be issued. New connections are allowed if the CQSDISC request is issued with CQSSHUT=YES, but they are not allowed if the CQSSHUT request is issued.

**Tuning to improve CQS performance**

You can improve CQS performance by carefully selecting the parameters you use with the CQSQUERY, CQSDEL, and CQSINFRM requests.

**Related concepts:**

Chapter 2. CQS client requests

CQS clients communicate with the CQS address space using a general-use interface consisting of a number of assembler macros, called CQS requests. CQS clients use these requests to communicate with the CQS and manipulate client data on shared coupling facility structures. You can use these requests to write or maintain a CQS client.

You do not need to use these requests if you are using an IBM-supplied client, such as an IMS control region.

Some CQS requests support wildcard parameters. Wildcard parameters allow you to specify multiple resources whose names match the wildcard parameter mask. The size of a wildcard parameter can be from one character to the maximum number of characters supported for the resource. The alphanumeric name can include one or more specialized characters and an asterisk or percent sign. An asterisk can be replaced by zero, one, or more characters to create a valid resource name. A percent sign can be replaced by exactly one character to create a valid resource name. The wildcard parameter asterisk (*) represents 'ALL'. However, depending on the installation, other wildcard parameters can mean all. For example, the wildcard parameter %%%% means ALL to an installation whose resource names are all 4 characters long.

This topic contains General-use Programming Interface information.

Example of using a CQS request: CQSREAD

The following example shows how you can use a CQSREAD request for a client subsystem.

```
* FUNCTION: USE CQSREAD REQUEST TO RETRIEVE A MESSAGE FROM SHARED QUEUES.
* THE CALLER OF THIS MODULE PASSES THE ADDRESS AND SIZE OF A BUFFER. IF THIS MODULE ENDS WITH RC=0, THAT BUFFER HOLDS THE DATA OBJECT OR PARTIAL DATA. IF THIS MODULE ENDS WITH A NON-ZERO RC, THE BUFFER'S CONTENTS ARE UNPREDICTABLE.
* REGISTERS ON ENTRY:
  R2 - READ OBJECT BUFFER ADDRESS (BUFFER TO READ OBJECT INTO)
  R3 - SIZE OF READ OBJECT BUFFER
  R4 - CQS REGISTRATION TOKEN ADDRESS
  R5 - CQS CONNECT TOKEN ADDRESS

16  System Programming APIs
CQSBRWSE request

The CQSBRWSE request retrieves information from a specified queue or resource structure.

Format

BROWSE function

Use the BROWSE function of a CQSBRWSE request to retrieve a copy of a data object from a specific queue.
A:
QTYPE=COLD-CLDTOKEN=coldqueuetokenaddress
QNAME=queuenameaddress
CLIENT=clientsnameaddress

BRWSOBJS function
Use the BRWSOBJS function of a CQSBRWSE request to browse one or more resource data objects of a specified type from a resource structure.

CQSBRWSE—FUNC=BRWSOBJS—CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress—PARM=parmaddress—BRWTOKEN=browsetokenaddress
LIST=resourcelistaddress—COUNT=resourcelistcount
LISTVER=LISTVERSION
BUFFER=bufferaddress—BUFSIZE=buffersize—OBJSIZE=dataobjectsizeaddress
RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress
ECB=ecbaddress

COMPLETE function
Use the COMPLETE function of a CQSBRWSE request to indicate to CQS that a CQSBRWSE request associated with a particular browse token is complete.

CQSBRWSE—FUNC=COMPLETE—CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress—PARM=parmaddress—BRWTOKEN=browsetokenaddress
RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress
ECB=ecbaddress

CONTINUE function of CQSBRWSE
Use the CONTINUE function of a CQSBRWSE request if a previous CQSBRWSE request retrieved partial data and you want to retrieve the rest of the data object.

CQSBRWSE—FUNC=CONTINUE—CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress—PARM=parmaddress—BRWTOKEN=browsetokenaddress
BUFFER=bufferaddress—BUFSIZE=buffersize—OBJSIZE=dataobjectsizeaddress
**DSECT function**

Use the DSECT function of a CQSBRWSE request to include equate (EQU) statements in your program for the CQSBRWSE parameter list length and CQSBRWSE return and reason codes.

**Usage notes**

A CQSBRWSE FUNC=BROWSE request retrieves a copy of a data object from a specific queue on a queue structure. The first CQSBRWSE FUNC=BROWSE request takes a snapshot of the data objects that meet the selection criteria and returns a copy of the first data object. The data object is neither deleted nor locked, and can be accessed by any subsequent CQS request. Each subsequent CQSBRWSE FUNC=BROWSE request retrieves a copy of the next data object. The data object is returned in the client buffer that is specified on the CQSBRWSE request. The size of the data object is passed to the client.

A browse token maintains the cursor position of the data objects that are being browsed. A CQSBRWSE FUNC=BROWSE request with a zero browse token returns the first data object. A CQSBRWSE FUNC=BROWSE request with a non-zero browse token retrieves the next data object on the queue that is associated with the browse token. If the data object that is returned is the last data object on the queue, CQS invalidates the browse token and frees any data structures associated with that browse token.

When a CQSBRWSE FUNC=BROWSE request is issued and the buffer that is passed is not large enough to hold the next data object, partial data is returned. The buffer is filled with as much of the data object as can fit. The CQSBRWSE FUNC=CONTINUE request retrieves the rest of the data object.

A CQSBRWSE FUNC=BRWSOBS request retrieves information about one or more data objects from a resource structure. The first CQSBRWSE FUNC=BRWSOBS request takes a snapshot of the data objects that meet the selection criteria and returns information about one or more of those data objects. The request returns as many data object entries as fit are returned in the client buffer that is specified on the CQSBRWSE request. Each subsequent CQSBRWSE FUNC=BRWSOBS request retrieves the next set of data object entries. A browse token maintains the cursor position of the data objects that are being browsed. A CQSBRWSE FUNC=BRWSOBS request with a zero browse token retrieves information about as many data objects as fit in the buffer. A CQSBRWSE FUNC=BRWSOBS request with a non-zero browse token retrieves the next group of data object entries. If the buffer contains information about the last data object being browsed, CQS invalidates the browse token and frees any data structures associated with that browse token.

A CQSBRWSE FUNC=COMPLETE request indicates to CQS that the CQSBRWSE request that is associated with a browse token is complete. The browse token from the prior CQSBRWSE request is required. CQS invalidates the browse token and
frees any data structures that are associated with it. The client should issue a
CQSBRWSE FUNC=COMPLETE request if it is not retrieving all of the data objects
on the specified queue.

The CQSBRWSE FUNC=CONTINUE request is not supported for a resource
structure because the CQSBRWSE FUNC=BRWSOBJ request does not return
partial data.

Attention:
• The cursor position of a CQSBRWSE FUNC=BROWSE or CQSBRWSE
  FUNC=CONTINUE request can be lost due to a CQS restart, a client restart,
  structure recovery, structure copy, or the browse table timing out. (The browse
  table times out after approximately one hour.)
• A CQSBRWSE request is not recoverable across a CQS or client failure. The
  client must reissue the CQSBRWSE request after such a failure.
• The data object is not locked on a CQSBRWSE request, so one or more of the
  objects might be snapped by the first CQSBRWSE FUNC=BROWSE request and
  no longer be available because of another CQSREAD or CQSDEL request.
• If overflow threshold processing occurs after the initial CQSBRWSE
  FUNC=BROWSE request and the queue is moved to the overflow structure, any
  subsequent CQSBRWSE FUNC=BROWSE request with browse token results in
  an error that indicates that no objects were found. Reissue the CQSBRWSE
  FUNC=BROWSE request with a browse token of zeroes, so that CQS can take a
  snapshot of the queue on the overflow structure. QSMOVE request, or overflow
  threshold processing. The CQSBRWSE FUNC=BROWSE simply skips objects that
  are no longer available.
• If the current position is lost because a browse table times out, a CQSBRWSE
  FUNC=CONTINUE request is rejected.

Parameters

BRWTOKEN=browsetokenaddress
Input and output parameter that specifies the address of the 16-byte browse
token. The browse token maintains the cursor position of the data objects that
are being browsed.

Set the browse token to zero on the initial CQSBRWSE request. Pass the
browse token that is returned by CQS on a CQSBRWSE FUNC=BROWSE or
FUNC=BRWSOBJ request as input on a subsequent CQSBRWSE=BROWSE,
CQSBRWSE=CONTINUE, CQSBRWSE=COMPLETE, or
CQSBRWSE=BRWSOBJ request.

On output, the browse token uniquely identifies the current data object that is
being browsed, which is returned in the buffer identified by the BUFFER
parameter.

For a CQSBRWSE FUNC=CONTINUE request, a CQSBRWSE
FUNC=COMPLETE request, or a subsequent CQSBRWSE FUNC=BROWSE
request, the BRWTOKEN parameter is an input parameter that specifies the
browse token returned by CQS on the prior CQSBRWSE FUNC=BROWSE
request.

BUFFER=bufferaddress
4-byte input parameter that specifies the address of a client buffer that holds
information that is retrieved about one or more data objects.

For a CQSBRWSE FUNC=BROWSE request, the client buffer contains a copy of
the data object retrieved from the queue on a queue structure.
For a CQSBRWSE FUNC=BRWSOBJ request, the client buffer contains the count of data object entries and one or more data object entries. Each data object entry contains information about one resource data object that is retrieved from the resource structure. Each data object entry contains information about a browsed data object such as the resource ID, the completion code, resource ID status, version, owner, client data1, optional client data2, and user data that was passed in the input list. If the size of the information is greater than the buffer size passed by the client, the buffer is filled with as many resource entries as can fit. The BUFFER is mapped by the CQSBRWSB DSECT.

The resource ID status indicates how the resource ID in the data object entry is associated with the input parameter. With this information, you can tie the input parameter to the data object entries that are generated in the output buffer. Possible resource ID statuses are:

**Specific parameter**
A specific resource ID. This data object entry contains the resource ID that matches the input parameter.

**Wildcard parameter**
A wildcard parameter was specified. This data object entry contains the wildcard parameter and a completion code. This data object entry does not contain information about a specific resource ID. If the completion code is zero, one or more wildcard match list entries follow.

**Wildcard match**
A wildcard parameter was specified. This data object contains information about one resource ID that matches the input wildcard parameter. All wildcard match list entries follow contiguously after a wildcard parameter list entry.

Possible completion codes are:

X'00000000'
Request completed successfully.

X'00000020'
The Resourceid parameter is invalid. The name type must be a decimal number from 1 to 255.

X'00000024'
CQS internal error.

X'00000040'
No resources matching either resource ID, resource type, owner, or some combination of these, were found.

**BUFSIZE=buffersize**
Four-byte input parameter that specifies the size of the client buffer.

**CLDTOKEN=coldqueuetokenaddress**
Output parameter that specifies the address of the 16-byte cold-queue token for the data object, which, along with the UOW, identifies an object on the cold queue.

You can use the cold-queue token and unit of work (UOW) on a CQSRECVR request to retrieve or delete objects on the cold queue.

**CLIENT=clientnameaddress**
4-byte output parameter that specifies the address of an 8-byte field to contain
the name of the client that locked the data object with a CQSREAD request. This parameter is valid only when the QTYPE=COLD parameter is specified.

CONTOKEN=connecttokenaddress
Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

COUNT=resourcelistcount
4-byte input parameter that specifies the number of entries in the resource list.

CQSTOKEN=cqstokenaddress
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

ECB=ecbaddress
4-byte input parameter that specifies the address of the z/OS event control block (ECB) that is used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise, it is processed synchronously.

LIST=resourcelistaddress
Address of a variable size input parameter that specifies a resource list that contains one or more entries. Each entry is a separate browse request. The client must initialize some fields in each entry before issuing the CQSBRWSE request. Other fields are returned by CQS when the request completes.

The CQSBRWSL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following parameters:

resourceid
12-byte input field that contains the unique identifier of the resources to be browsed. The resource ID can be a wildcard parameter. The resource ID is unique in the IMSplex. The resource ID consists of a 1-byte name type, followed by an 11-byte client-defined name. The name type ensures uniqueness of client-defined names for resources with the same name type. Resources of different resource types might have the same name type. A valid value for the name type is a decimal number from 1 to 255. The client-defined name has meaning to the client and consists of alphanumeric characters. If you use a wildcard parameter to specify the resource ID, also specify the resource type, to enhance performance. You must specify the resource ID, resource type, or both.

resourcetype
1-byte input field that specifies the resource type. The resource type is a client-defined physical grouping of resources on the resource structure. Valid values for the resource type are decimal numbers from 1 to 255. If the resource type is greater than the maximum number of resource types defined by CQS (11), it is folded into one of the existing resource types. You must specify the resource type, resource ID, or both.

reserved
3-byte reserved field.

owner
8-byte input parameter that identifies the owner of the resource data.
objects to be browsed. The CQSBRWSE request returns only those resource
data objects that are owned by the specific owner. owner is an optional
parameter.

**options**

4-byte input parameter that specifies browse options. Possible options are:

- X'80000000'
  
  Return data2 for the browsed data objects.

**userdata**

Four-byte input parameter that specifies user data. This user data
is passed on output for each data object that matches the input
resource ID parameter.

**LISTVER=1 | listversion**

Input parameter that specifies an equate for the list version. The default value
is 1. Use the DSECT function of a CQSBRWSE request to include equate (EQU)
statements in your program for the CQSBRWSE list versions.

**OBJSIZE=dataobjectsizeaddress**

Output parameter that specifies the address of a 4-byte area to store the size of
a data object or data object entry.

If a CQSBRWSE FUNC=BROWSE request is issued and the size of the data
object is greater than the buffer size passed by the client, the buffer is filled
with as much of the data object as fits. The request receives a return and
reason code indicating partial data returned. The size of the data object is
returned in the location specified by the OBJSIZE parameter. If the size of the
data object is less than or equal to the size of the buffer, the data object is
moved into the buffer and the remainder of the buffer is not changed.

If a CQSBRWSE FUNC=BRWSOBS request is issued, as many data object
entries as can fit are moved into the buffer. The client must then issue a
subsequent CQSBRWSE FUNC=BRWSOBS request to retrieve the next data
object entries. If the buffer is not large enough to hold the next data object
entry, the request receives a return and reason code indicating the buffer is too
small. The size of the next data object entry to be returned is saved in the
location specified by the OBJSIZE parameter.

**PARM=paraddress**

4-byte input parameter that specifies the address of a parameter list used by
the request to pass parameters to CQS. The length of the storage area must be
at least equal to the EQU value CQSBRWSE_PARM_LEN (defined using the
FUNC=DSECT request).

**QNAME=queuenameaddress**

4-byte output parameter that specifies the address of a 16-byte queue name
field.

For a CQSBRWSE request that specifies the QTYPE=COLD and CLDTOKEN
parameters, the queue name field is an output field to contain the original
client queue name for the data object being returned. This client queue name
contained the data object before it was moved to the cold queue.

For all other CQSBRWSE requests, the queue name field is an input field that
specifies the queue name from which the data object is retrieved for all
CQSBRWSE requests.
QTYPE=COLD
Input parameter that specifies the queue type from which the data object is to be retrieved. COLD indicates that the data object is to be retrieved from the cold queue.

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSBRWSE return code.

If the return code in register 15 is a non-zero value, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

RSNCODE=reasoncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSBRWSE reason code.

TIMESTAMP=timestampaddress
4-byte output parameter that specifies the address of an 8-byte field to contain the time stamp when the data object was placed on the queues.

UOW=uowaddress
Output parameter that specifies the address of a 32-byte area to hold the unit of work (UOW) of the data object retrieved from the queue. The UOW is a unique identifier generated by the client that stored the data object on the queue (CQSPUT request).

Return and reason codes

The following table lists the return and reason code combinations that can be returned for CQSBRWSE requests. Use a CQSBRWSE FUNC=DSECT request to include equate (EQU) statements in your program for the return and reason codes.

<table>

CQSCHKPT request

Use the CQSCHKPT request to initiate either a CQS system checkpoint or a structure checkpoint.

Format for CQSCHKPT

CHKPTSTR function of CQSCHKPT

You use the CHKPTSTR function of a CQSCHKPT request to initiate a CQS structure checkpoint for a queue structure. Structure checkpoint is not supported for a resource structure.

►►CQSCHKPT—FUNC=CHKPTSTR—CQSTOKEN=cqstokenaddress—PARAM=parmaddress—COUNT=count—LIST=listaddress—ECB=ecbaddress—RETCODE=returncodeaddress—RSCODE=reasoncodeaddress

Chapter 2. CQS client requests
CHKPTSYS function of CQSCHKPT

Use the CHKPTSYS function of a CQSCHKPT request to initiate a CQS system checkpoint.

DSECT function of CQSCHKPT

Use the DSECT function of a CQSCHKPT request to include equate (EQU) statements in your program for the CQSCHKPT parameter list length and CQSCHKPT return and reason codes.

Usage of CQSCHKPT

For a structure checkpoint, CQS dumps the queues to DASD for each structure specified in the checkpoint list. If the structure is currently in overflow mode, the overflow structure is also dumped to DASD.

For a system checkpoint, CQS logs the internal tables for each structure specified in the checkpoint list. If the structure is currently in overflow mode, CQS also logs the internal tables for the overflow structure.
Parameter descriptions

**COUNT=count**
4-byte input parameter that specifies the number of entries in the checkpoint list.

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**
4-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LIST=listaddress**
4-byte input parameter that specifies the address of the checkpoint list. The checkpoint list should contain an entry for each of the structures for which the client requests a checkpoint.

The CQSCHKPL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following parameters:

**connecttoken**
16-byte input parameter that specifies the connect token returned by the CQSCONN request. The connect token uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. This parameter is required.

**compcode**
4-byte output field to receive the completion code from the request. Possible completion codes are:

- X'00000000'
  Completed successfully.

- X'00000004'
  Connect token is invalid.

- X'00000008'
  CQS checkpoint request not allowed until CQS restart has successfully completed a system checkpoint.

- X'0000000C'
  A CQSRSYNC is required for this structure.

- X'00000010'
  Checkpoint already in progress for structure.

- X'00000014'
  Structure is inaccessible. Retry request later.

- X'00000018'
  CQS internal error.

- X'00000020'
  CQSCHKPT FUNC=CHKPTSTR is invalid for a resource structure.

**LISTVER=1 | listversion**
Input parameter that specifies an equate for the list version. Use the DSECT
function of a CQSCHKPT request to include equate (EQU) statements in your
program for the CQSCHKPT list versions.

**PARM=parmaddress**

4-byte input parameter that specifies the address of a parameter list used by
the request to pass parameters to CQS. The length of the storage area must be
at least equal to the EQU statement value CQSCHKPT_PARM_LEN (defined
using the FUNC=DSECT request).

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the
CQSCHKPT return code.

If the return code in register 15 is nonzero, the values in the return and reason
code fields are invalid, because the CQS interface detected an error and was
unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the
CQSCHKPT reason code.

### Return and reason codes for CQSCHKPT

The following table lists the return and reason code combinations that can be
returned for CQSCHKPT requests. Use a CQSCHKPT FUNC=DSECT request to
include equate statements in your program for the return and reason codes.

<table>

<td>X'00000430'</td>
<td>No CQS address space.</td>
</tr>
</tbody>
</table>

**Related concepts:**

[Using CQS system checkpoint (System Administration)]

### CQSCONN request

The CQSCONN request connects a client to one or more coupling facility
structures.
Format for CQSCONN

CONNECT function of CQSCONN

You use the CONNECT function of a CQSCONN request to connect to one or more coupling facility structures. The coupling facility structures can be queue structures or resource structures.

```
CQSCONN FUNC=CONNECT CQSTOKEN=cqstokenaddress PARM=parmaddress
  COUNT=count LISTSIZE=listsize
  FCCQSSSN=fccqsssnaddress
  LIST=listaddress ECB=ecbaddress RETCODE=returncodeaddress
  RSNCODE=reasoncodeaddress LISTVER=listversion
```

DSECT function of CQSCONN

Use the DSECT function of a CQSCONN request to include equate (EQU) statements in your program for the CQSCONN parameter list length and CQSCONN return and reason codes.

```
CQSCONN FUNC=DSECT
```

Usage of CQSCONN

The CQSCONN request connects a client to one or more coupling facility structures. The client specifies a connect list containing one or more list entries, for which each entry is a separate connect request. If the connection to a structure is successful, a connect token is returned to the client, representing the connection to the structure. The client must specify this token on all subsequent CQS requests for that structure. A maximum of 32 clients can use a CQS address space to connect to a coupling facility structure.

Restriction: The CQSCONN request is not logged for resource structures and does not support the FCCQSSSN keyword. The CQSCONN request does not support the following connect list parameters for a resource structure:

- `structureattributes`
- `overflowstructurename`
- `structureinformexit`
- `structureinformparm`
- `qtypecnt`
- `qtypelist`

A CQSCONN FUNC=CONNECT request must be issued after a CQSREG FUNC=REGISTER request and before any other CQS requests. Also, after a CQS
abnormal termination and restart, and after the client has reregistered with CQS, a CQSCONN FUNC=CONNECT request is required before the client can issue any other CQS requests.

Parameter Description:

**COUNT=**count
Four-byte input parameter that specifies the number of list entries in the connect list.

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**ECB=**ecbaddress
Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**FCQSSSN=**fccqsssnaddress
Four-byte input parameter that specifies the address of the failed client CQS subsystem. When one client takes over for another client, this is the SSN of the CQS that was connected to the failed client.

This keyword is not applicable to a resource structure.

**LIST=**listaddress
Four-byte input parameter that specifies the address of a connect list containing one or more entries. Each entry is a separate request to connect a client to a coupling facility structure. Some fields for each entry must be initialized by the client prior to the CQSCONN request. Other fields are returned by CQS upon completion of the CQSCONN request.

The CQSCONNL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

**Note:** All fields in the CQSCONNL DSECT currently documented as “Not Used” must be set to zero by the caller of CQSCONN.

Each list entry contains the following parameters:

**compcode**
Four-byte output field to receive the completion code from the request. Possible completion codes are:

- X’00000000’
  Client connection successful. A connect token is returned to the client.

- X’00000004’
  The client is already connected to the structure through this CQS. A connect token is returned to the client.

- X’00000008’
  strucname is invalid.

- X’00000010’
  The Structure Event exit routine address was not specified.
structure through one CQS. The client is not connected to the structure through this CQS. This does not affect the status of a client connection with another CQS.

X'00000014'
  CQS internal error.

X'00000018'
  The client specified the FCCQSSSN= parameter to connect to the structure to take over work for a failed client. CQS could not find a valid system-checkpoint log token for the CQS that was connected to the failed client. CQS issued message CQS0033A, to which the operator replied REJECT.

X'0000001C'
  The user ID of the client address space is not authorized to connect to the structure.

X'00000020'
  structureinformexit was specified but is not allowed for a resource structure.

X'00000024'
  structureinformparm was specified but is not allowed for a resource structure.

X'0000002C'
  structureattributes was specified but is not allowed for a resource structure.

X'00000030'
  Qtype was specified but is not allowed for a resource structure.

X'00000034'
  FCCQSSSN was specified but is not allowed for a resource structure.

structureattributes
  Four-byte input and output parameter field that contains the structure attributes.

  +0  Flag byte 1, with the following bits defined:

  X'80'
    Indicates the specification of the structure “wait for rebuild” attribute. The first client in the sysplex to connect to a structure defines this attribute for all clients. It is returned on the connect request to allow clients to verify that the attribute is set correctly for their needs because it might have been set by a prior client connection.

    The value specified for structureattributes remains in effect for the life of the structure, and cannot be changed.

    When set to 0, indicates that client requests to write and retrieve data objects from the structure do not wait for a rebuild to complete.

    When set to 1, indicates that client requests to write and retrieve data objects from the structure must wait for a rebuild to complete.

  X'40'
    Output flag returned by CQS. For queue structures only, this flag indicates whether the structure is a
non-recoverable structure (whether RECOVERABLE=NO was specified in the CQSSGxxx PROCLIB member for the structure). This flag is set to 1 if the structure is a non-recoverable structure; otherwise, it is set to 0.

This flag is not applicable to a resource structure.

The remaining bits in this byte are not used, and must be set to zero.

+1 The next 3 bytes are not used, and must be set to zero.

structuretype
One-byte output parameter field that specifies the structure type as either a queue structure or a resource structure.

structureversion
Eight-byte output parameter field that specifies the structure version of the structure to which the client just connected.

structurename
Sixteen-byte input parameter field that contains the name of the structure to which the client wants to connect. This parameter is required.

overflowstructurename
Sixteen-byte output parameter field to receive the name of the overflow structure, if one was defined to CQS in the CQS Global Structure Definition PROCLIB member, CQSSGxxx.

This parameter is not applicable to a resource structure.

connecttoken
Sixteen-byte output parameter field to receive the connect token that uniquely identifies the client’s connection to a particular coupling facility structure managed by this CQS.

structureeventexit
Four-byte input parameter field that contains the Structure Event exit routine address. This parameter is required.

structureeventparm
Four-byte input parameter field that contains client data that CQS passes to the Structure Event exit routine every time the exit is called. This parameter is optional; set it to zero if you do not want to pass any data to the exit routine.

structureinformexit
Four-byte input parameter field that contains the Structure Inform exit routine address. This parameter is optional; set it to zero if you do not have a Structure Inform exit routine.

This parameter is not applicable to a resource structure.

structureinformparm
Four-byte input parameter field that contains client data that CQS passes to the Structure Inform exit routine every time the exit is called. This parameter is optional; set it to zero if you do not want to pass any data to the exit routine.

This parameter is not applicable to a resource structure.

qtypecnt
Four-byte input parameter field that contains the number of queue
type entries in the queue type list. This parameter is optional; set it to zero if you do not have any entries in the queue type list.

This parameter is not applicable to a resource structure.

**qtypelst**

Variable length input area for the queue type list.

This parameter is not applicable to a resource structure.

The length of this area is equal to the value specified for `qtypecnt`. Each queue type entry is a 1-byte value of a queue type that should *not* be moved to the overflow structure if the primary structure goes into overflow mode. This parameter is optional.

When using version 1 of the CQSCONN parameter list (the default), build the queue type list starting at label `CNLQTYPL` in the CQSCONNL DSECT, which maps the list entry. When using version 16 of the CQSCONN parameter list, build the queue type list starting at label `CNLQTYPL_V16`.

After a queue type is defined, it remains in effect for the life of the structure, and is not moved to the overflow structure.

If no queue types are listed, the default is for all queue types to be eligible for overflow. This list should only be included if there are certain queue types the client knows should not be moved (perhaps based on the client’s use of the queue types).

**Recommendation:** Clients should exclude from processing those queue types that allow multiple objects with the same queue name and UOW. CQS cannot recover multiple objects with the same queue name and UOW that are allowed to be moved to the overflow structure.

**logstreamname**

Twenty-six-byte output parameter field to receive the name of the z/OS log stream associated with the CQS structure. This field is set to all blanks for non-recoverable queue structures and for resource structures.

This field is present only for CQSCONN lists at version 16 or later.

**logstreamstructurename**

Sixteen-byte output parameter field to receive the name of the CF structure associated with the z/OS log stream that is associated with the CQS structure. This field is set to all blanks for non-recoverable queue structures, resource structures, and structures with DASD-only z/OS log streams.

This field is present only for CQSCONN lists at version 16 or later.

**LISTSIZE=listsize**

Four-byte input parameter that specifies the size of the connect list. `listsize` specifies the total length of all entries in the list, not the length of a single entry.

**LISTVER=1 | listversion**

Input parameter that specifies the parameter list version. Use the DSECT function of the CQSCONN request to include equate (EQU) statements in your program for the CQSCONN list versions and lengths. The following parameter list versions are supported:

1 EQU symbol is `CNL_LVER1`. This is the default parameter list version.
This version of the parameter list includes all fields documented under the LIST= parameter except for those that are specifically noted as being present only in a higher list version. The minimum length of a version 1 parameter list entry is CNL_MINLNV1 bytes. Queue type entries, if present, begin at label CNLQTYPL in the CQSCONNL DSECT, mapping the list entry.

16 EQU symbol is CNL.Lerp16. A version 16 parameter list contains additional output fields beyond the fields present in a version 1 parameter list. These additional fields are documented under the LIST= parameter and are returned only when a version 16 format parameter list is passed. The minimum length of a version 16 parameter list entry is CNL_MINLNV16 bytes. Queue type entries, if present, begin at label CNLQTYPL_V16 in the CQSCONNL DSECT, mapping the list entry.

**PARM=parmaddress**

Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSCONN_PARM_LEN (defined using the FUNC=DSECT request).

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSCONN return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSCONN reason code.

**Return and reason codes for CQSCONN**

The following table lists the return and reason code combinations that can be returned for CQSCONN requests. Use a CQSCONN FUNC=DSECT request to include equate statements in your program for the return and reason codes.

### CQSDEL request

A CQSDEL request deletes one or more data objects from a queue structure or a resource structure.

#### Format for CQSDEL

**DELETE function of CQSDEL**

Use the DELETE function of a CQSDEL request to delete one or more data objects from a queue structure or a resource structure.

```
►► CQSDEL—FUNC=DELETE—CQSTOKEN=cqstokenaddress

►-CONTOKEN=connecttokenaddress—PARM=parmaddress—COUNT=count

►-LIST=listaddress—ECB=ecbaddress—RETCODE=returncodeaddress

►-RSNCODE=reasoncodeaddress

►-LISTVER=1—LISTVER=listversion
```

**DSECT function of CQSDEL**

Use the DSECT function of a CQSDEL request to include equate (EQU) statements in your program for the CQSDEL parameter list length and CQSDEL return and reason codes.

```
►► CQSDEL—FUNC=DSECT
```

### Usage of CQSDEL

A CQSDEL request deletes one or more data objects from a queue structure or a resource structure. The client specifies a delete list that contains one or more list
entries, for which each list entry is a separate delete request (either by lock token, by queue name, by queue name and UOW, by resource ID, or by resource type and owner). Each list entry is processed separately and receives its own completion code.

Parameter description:

**CONTOKEN=connecttokenaddress**
Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**COUNT=count**
A 4-byte input parameter that specifies the number of list entries in the delete list.

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**
A 4-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise, it is processed synchronously.

**LIST=listaddress**
A 4-byte input parameter that specifies the address of a delete list containing one or more entries. Each entry is a separate delete request. Some fields in each entry must be initialized by the client prior to the CQSDEL request. Other fields are returned by CQS upon completion of the request.

The CQSDELL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following parameters:

**deletetype**
One-byte input parameter field that contains the delete type. This is a required parameter. deletetype can have one of the following values:

1. Delete by lock token.
2. Delete by queue name.
3. Delete by queue name and unit of work.
4. Delete by resource ID and version.
5. Delete by resource type with the specified owner.

**Recommendation:** For better performance, use delete type 1 or delete type 2 because they are more efficient than delete type 3.

**deleteqpos**
One-byte input parameter field that specifies either that all data objects are to be deleted or the position on the queue of data objects to be deleted. This parameter is only used for delete type 2. deleteqpos can have one of the following values:

1. Delete all data objects on the queue.
2. Delete the first data object on the queue.

System Programming APIs
Delete the last data object on the queue.

The locktoken, deleteqpos, and uow fields are mutually exclusive.

reserved
A 2-byte reserved field.

objdelcnt
A 4-byte output parameter field to receive the number of data objects deleted.

compecode
A 4-byte output field to receive the completion code from the request. Possible completion codes are:

X'00000000'
Request completed successfully.

X'00000004'
Invalid deleteqpos (Delete type 2).

X'00000008'
Invalid deletetype.

X'0000000C'
Invalid locktoken (Delete type 1).

X'00000010'
Invalid queuename (Delete type 2 or type 3).

X'00000014'
Invalid uow (Delete type 3).

X'0000001C'
Structure is inaccessible. Try the request again later.

X'00000020'
CQS internal error.

X'00000024'
Data object not found on queue (Delete type 2) or on queuename for UOW (Delete type 3), or on resource structure (Delete type 4). It is up to the client to determine whether this case should be treated as an error or not.

X'00000028'
Delete type 1, 2, or 3 is invalid for a resource structure.

X'00000032'
Delete type 4 or 5 is invalid for a queue structure.

X'00000036'
Resourceid is invalid. The name type must be a decimal number between 1 - 255.

X'00000040'
Version is invalid. The version must be a number greater than zero.

X'00000044'
Version does not match that of an existing resource.

X'00000048'
Resourcetype is invalid. The resource type must be a decimal number between 1 - 255.
**locktoken**
A 16-byte input parameter field that contains the lock token. The lock token is returned by the CQSREAD request. This parameter is only used for delete type 1.

The `locktoken`, `deleteqpos`, and `uow` fields are mutually exclusive. The `locktoken` and `queue` fields are also mutually exclusive.

**queue**
A 16-byte input parameter field that contains the queue name. This parameter is only used for delete types 2 and 3.

The `locktoken` and `queue` fields are mutually exclusive.

**uow**
A 32-byte input parameter that contains the unit of work. This parameter is only used for delete type 3.

The `locktoken`, `deleteqpos`, and `uow` fields are mutually exclusive.

**resourceid**
A 12-byte input parameter that contains the unique identifier of the resource data object to delete. This parameter is required for delete type 4. The `resourceid`, `locktoken`, `queue`, and `resource` fields are mutually exclusive.

**version**
An 8-byte input and output parameter that contains the version of the resource to be deleted. The version specified must match the version of the resource for the delete request to succeed. The version is a count of the number of times the resource has been updated. This parameter is required for delete type 4. If the delete fails because of version mismatch, the version is returned as output.

**resourcetype**
A 1-byte input parameter that contains the resource type. The resource type is a client-defined physical grouping of resources on the resource structure. Valid values for the resource type are decimal numbers from 1 to 255. If the resource type is greater than the maximum number of resource types defined by CQS (11), it is folded into one of the existing resource types. This parameter is required for delete types 4 and 5. Specify zero to delete all resources of a resource type that are not owned.

**reserved**
A 3-byte reserved field.

**owner**
An 8-byte input parameter that specifies the owner for which to delete resources of the specified resource type. This parameter is required for delete type 5.

**LISTVER=1** | **listversion**
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSDEL request to include equate (EQU) statements in your program for the CQSDEL list versions.

**PARM=parmaddress**
A 4-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSDEL_PARM_LEN (defined using the FUNC=DSECT request).
RETCODE=\texttt{returncodeaddress}

Output parameter that specifies the address of a 4-byte field to contain the CQSDEL return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

RSNCODE=\texttt{reasoncodeaddress}

Output parameter that specifies the address of a 4-byte field to contain the CQSDEL reason code.

Return and reason codes for CQSDEL

The following table lists the return and reason code combinations that can be returned for CQSDEL requests. Use a CQSDEL FUNC=DSECT request to include equate statements in your program for the return and reason codes.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|l|}
\hline
Return code & Reason code & Meaning \\
\hline
X'00000000' & X'00000000' & Request completed successfully. \\
X'00000008' & X'00000210' & \texttt{cqstoken} is invalid. \\
X'00000008' & X'00000214' & \texttt{connecttoken} is invalid. \\
X'00000008' & X'00000218' & FUNC is invalid. \\
X'00000008' & X'00000250' & \texttt{count} is invalid. \\
X'00000008' & X'00000254' & \texttt{listaddress} is invalid. \\
X'00000008' & X'00000284' & Parameter list version is invalid. \\
X'00000008' & X'00000288' & List version is invalid. \\
X'0000000C' & X'00000300' & Request succeeded for at least one, but not all, list entries. See \texttt{compcode} for individual errors. \\
X'0000000C' & X'00000304' & Request failed for all list entries. See \texttt{compcode} for individual errors. \\
X'00000010' & X'00000400' & A CQSRSYNC is required for this structure. \\
X'00000010' & X'00000430' & No CQS address space. \\
X'00000014' & X'00000500' & CQS internal error. \\
\hline
\end{tabular}
\caption{CQSDEL return and reason codes}
\end{table}

CQSDEREG request

The CQSDEREG request deregisters a client from CQS and invalidates the CQSTOKEN.

Format for CQSDEREG

\textbf{DEREGISTER function of CQSDEREG}

A CQSDEL request deletes one or more data objects from a queue structure or a resource structure.

\begin{verbatim}
CQSDEREG—FUNC=DEREGISTER—CQSTOKEN=cqstokenaddress—PARM=parmaddress
\end{verbatim}
DSECT function of CQSDEREG

Use the DSECT function of a CQSDEREG request to include equate (EQU) statements in your program for the CQSDEREG parameter list length and CQSDEREG return and reason codes.

Usage of CQSDEREG

The CQSDEREG request deregister a client from CQS and invalidates the CQSTOKEN. Prior to issuing this request, the client should issue the CQSDISC request to disconnect from all structures to which the client has a connection. When this request is successfully completed, no subsequent requests can be made to CQS until a CQSREG request has been made to get a new CQSTOKEN.

Parameter Description:

CQSTOKEN=cqstokenaddress
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSDEREG_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSDEREG return code. The CQSDEREG return code is returned both in this field and in register 15.

RSNCODE=reasoncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSDEREG reason code. The CQSDEREG reason code is returned both in this field and in register 0.

Return and reason codes for CQSDEREG

The following table lists the return and reason code combinations that can be returned for CQSDEREG requests.

<table>

</tbody>
</table>

CQSDISC request

The CQSDISC request allows a client to disconnect from one or more coupling facility structures.

Format for CQSDISC

DISCABND function of CQSDISC

You use the DISCABND function of a CQSDISC request while the client is terminating abnormally to terminate client connections to all coupling facility structures.

\[ \text{CQSDISC} \quad \text{FUNC=} \text{DISCABND} \quad \text{CQSTOKEN=} \text{cqstokenaddress} \quad \text{PARM=} \text{parmaddress} \]

\[ \text{A:} \]

\[ \text{CQSSHUT=} \text{YES} \quad \text{CQSSHUT=} \text{NO} \]

DISCNORM function of CQSDISC

Use the DISCNORM function of a CQSDISC request while the client is terminating normally to terminate client connections to one or more coupling facility structures.

\[ \text{CQSDISC} \quad \text{FUNC=} \text{DISCNORM} \quad \text{CQSTOKEN=} \text{cqstokenaddress} \quad \text{PARM=} \text{parmaddress} \]
DSECT function of CQSDISC

Use the DSECT function of a CQSDISC request to include equate (EQU) statements in your program for the CQSDISC parameter list length, CQSDISC return and reason codes, and literals that can be used to build the OPTWORD1 parameter.

Usage of CQSDISC

Restriction: The CQSDISC request does not support structure attributes for resource structures.

The CQSDISC request allows a client to disconnect from one or more coupling facility structures. CQS disconnects client resources associated with the structures. The client needs to issue a CQSDEREG request to completely disconnect from CQS.

A CQSDISC FUNC=DISCABND request, used when the client is terminating abnormally, terminates client connections to all coupling facility structures.

A CQSDISC FUNC=DISCNORM, used when the client is terminating normally, terminates client connections to one or more coupling facility structures. The client specifies a disconnect list containing one or more list entries, for which each entry is a separate disconnect request. As each structure disconnect is completed, the connect token for that structure is invalidated and can no longer be used by the client.

Parameter Description:

COUNT=count
Four-byte input parameter that specifies the number of list entries in the disconnect list.

CQSSHUT=YES | NO
Input parameter that indicates whether or not the CQS address space should be shut down after all clients have disconnected.
If CQSSHUT=YES is specified, new clients continue to be allowed to issue CQSCONN requests. The CQSSHUT FUNC=QUIESCE request can be used to prevent new clients from issuing CQSCONN requests.

The CQSSHUT parameter cannot be used when the OPTWORD1 parameter is specified. If you specify OPTWORD1 instead of CQSSHUT, you can use the following equate (EQU) symbols to generate the value for the OPTWORD1 parameter:

- CQSDISC_SHUTYEQX CQSSHUT=YES
- CQSDISC_SHUTNEQX CQSSHUT=NO

CQSTOKEN=cqstokenaddress
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

ECB=ecbaddress
Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise the request is processed synchronously.

LIST=listaddress
Four-byte input parameter that specifies the address of a disconnect list containing one or more entries. Each entry is a separate request to disconnect a client from a coupling facility structure. Some fields in each entry must be initialized by the client prior to the CQSDISC request. Other fields are returned by CQS upon completion of the CQSDISC request.

The CQSDISCL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following:

connecttoken
Sixteen-byte input parameter that specifies the connect token that uniquely identifies the client’s connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request. This parameter is required.

structureattributes
Four-byte input parameter field that contains the structure attributes.

+0 Flag byte 1, with the following bits defined:

X'80'
When set to 0, indicates that CQS should not perform a structure checkpoint for the structure.

When set to 1, indicates that CQS should perform a structure checkpoint for the structure.

X'40'
When set to 0, indicates that CQS should not perform disconnect processing for the structure if there is any inflight work (locked objects) on the structure. If inflight work is found, CQS will set completion code X'00000008' in the compcode field, and will return a return code of X'0000000C', and a reason code of either X'00000300' or X'00000304' for the request.

When set to 1, indicates that CQS should disconnect from the structure, even if there is inflight work (locked objects) on the structure. If inflight work is found, CQS will set completion code X'00000008' in the compcode field, and
will return a return code of X'00000004', and a reason code of X'00000140' for the request, if no other errors in disconnect processing occur. Note that the return and reason code is a warning only; the disconnect processing is still performed.

The remaining bits in this byte are not used, and must be set to zero.

+1 The next 3 bytes are not used, and must be set to zero.

compcode
Four-byte output field to receive the completion code from the request. Possible completion codes are:

X'00000000'
Request completed successfully.

X'00000004'
connecttoken is invalid.

X'00000008'
The client has inflight work for the structure. If the X'40' bit in the first byte of the structureattributes parameter was set to one, the disconnect processing was successful for the structure, and this completion code is informational.

If the X'40' bit was zero, the disconnect processing was not done for this structure, and the CQS client should complete the inflight work before continuing.

X'0000000C'
Structure attributes are not allowed for a resource structure.

LISTVER=1 | listversion
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSDISC request to include equate (EQU) statements in your program for the CQSDISC list versions.

OPTWORD1=optionwordvalue
Four-byte input parameter that specifies the literals for this request. This parameter can be used instead of CQSSHUT. Equate (EQU) statements for the literal values are listed under the description of the CQSSHUT parameter. Equate statements can also be generated by using the DSECT function. The OPTWORD1 parameter cannot be used if CQSSHUT is specified.

Requirement: If you code the OPTWORD1 parameter, you must pass a value that is composed of one equate value for each literal value supported by this macro.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSDISC_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSDISC return code.
If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**
Output parameter that specifies the address of a 4-byte field to contain the CQSDISC reason code.

### Return and reason codes for CQSDISC

The following table lists the return and reason code combinations that can be returned for CQSDISC requests. Use a CQSDISC FUNC=DSECT request to include equate statements in your program for the return and reason codes.

**Table 12. CQSDISC return and reason codes**

</table>

### CQSINFRM request

The CQSINFRM request registers or deregisters interest for one or more queues on a specific coupling facility structure.

### Format for CQSINFRM

**DSECT function of CQSINFRM**

You use the DSECT function of a CQSINFRM request to include equate (EQU) statements in your program for the CQSINFRM parameter list length and CQSINFRM return and reason codes.
INFORM function of CQSINFRM

Use the INFORM function of a CQSINFRM request to register a client's interest in one or more queues on a specific coupling facility structure.

```plaintext
CQSINFRM FUNC=INFORM CQSTOKEN=cqstokenaddress PARM=parmaddress
COUNT=count LISTSIZE=listsize LIST=listaddress ECB=ecbaddress
RETCODE=returncodeaddress RSNCODE=reasoncodeaddress
LISTVER=1 LISTVER=listversion
```

UNINFORM function of CQSINFRM

Use the UNINFORM function of a CQSINFRM request to deregister a client's interest in one or more queues on a specific coupling facility structure it previously registered interest for.

```plaintext
CQSINFRM FUNC=UNINFORM CQSTOKEN=cqstokenaddress PARM=parmaddress
COUNT=count LISTSIZE=listsize LIST=listaddress ECB=ecbaddress
RETCODE=returncodeaddress RSNCODE=reasoncodeaddress
LISTVER=1 LISTVER=listversion
```

Usage of CQSINFRM

A client uses a CQSINFRM request to register or deregister interest for one or more queues on a specific coupling facility structure. When a queue goes from empty to non-empty, CQS notifies all clients that registered interest for the queue of the change in status by scheduling the Structure Inform Client exit routine.

Restriction: The CQSINFRM request is not supported for resource structures.

The client can issue CQSREAD or CQSBRWSE requests to retrieve data from a queue. A client can make data objects available on a queue using CQSPUT, CQSMOVE, or CQSUNLCK requests.
A client that has registered interest in a queue is only notified when the queue goes from empty to non-empty, or if a data object is available on the queue when the CQSINFRM request is issued. The client does not receive notification when additional data objects are placed on a non-empty queue.

After a client deregisters interest in a queue, it is no longer notified when one of the queues goes from empty to non-empty. Because client notifications occur asynchronously with CQSINFRM requests, the client should expect to be notified about new data objects that arrive between the time the client issues the CQSINFRM FUNC=UNINFORM request and the time CQS processes the request.

**Parameter Description:**

**COUNT=count**
Four-byte input parameter that specifies the number of structure list entries in the structure list.

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**
Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LIST=listaddress**
Four-byte input parameter that specifies the address of the structure list. The structure list is built in contiguous storage, and the size of the list must be specified using the LISTSIZE parameter. The structure list should contain an entry for each coupling facility structure for which the client will register or deregister interest. Each structure list entry must contain a list of the queues for which the client will register or deregister interest.

Each connect token in a structure list entry and queue name in the queue list entry must be initialized prior to the request. Upon completion of the request, CQS returns the structure completion code for the structure list and the queue completion code for the queue list.

The CQSINFL list entry DSECT maps the queue and structure list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each structure list entry contains the following parameters:

**connecttoken**
Sixteen-byte input parameter that specifies the connect token that uniquely identifies the client’s connection to CQS and a specific coupling facility structure. The connect token is returned by the CQSCONN request. This parameter is required.

**structurecompletioncode**
Four-byte output field to receive the completion code for the CQSINFRM request for the structure. Possible structure completion codes are:

- X'00000000'
  Request completed successfully.
X'00000004'  
Request completed successfully for all queues. At least one  
queue has work on it. See the queue completion code to  
determine which queues have work on them.

X'00000010'  
connecttoken is invalid.

X'00000014'  
queuelistcount is invalid.

X'00000018'  
Inform exit routine does not exist. The Structure Inform exit  
routine was not specified on CQSCONN request for structure.

X'00000020'  
Request completed successfully for at least one, but not all  
queues in queuelist. See queuecompletioncode for individual  
errors.

X'00000024'  
Request failed for all queues in queuelist. See  
queuecompletioncode for individual errors or successes.

X'00000030'  
A CQSRSYNC is required for this structure.

X'00000034'  
CQSINFRM is not allowed for a resource structure.

queuelistcount  
Four-byte input parameter that specifies the number of queues in the  
queue list. This parameter is required.

**Recommendation:**  For optimum performance, a client that registers  
interest in many queues should issue multiple CQSINFRM requests, in  
which each request lists no more than 1024 queues.

queuelist  
Variable length input area that contains one or more queue lists. A  
queue list, built by the client, should contain an entry for each queue  
on the structure for which the client will register or deregister interest.  
The queue names must be initialized prior to the request. This  
parameter is required.

Each queue list entry contains the following:

queuename  
Sixteen-byte input field that contains the name of the queue for  
which the client is registering interest. This parameter is  
required.

queuerequestflag  
One-byte input field that contains flags specific to this queue  
that can be set for this CQSINFRM request.

X'80'  Call the client Inform exit routine if there are data  
objects on the queue at the time the client issues the  
CQSINFRM FUNC=INFORM request. Applies only to  
CQSINFRM FUNC=INFORM requests.
queuecompletioncode

Four-byte output field to receive the completion code for the specified queue. Possible completion codes are:

X'00000000'
Request completed successfully.

X'00000040'
Work exists on queue.

X'00000044'
queue name is invalid.

X'00000048'
CQS internal error.

X'00000050'
Structure is full. No more event monitoring controls (EMC)s are available for queue registration.

X'00000054'
Structure is inaccessible. Retry request.

LISTSIZE=lists size

Four-byte input parameter that specifies the size of the structure list. The client builds the structure list and must specify the size of the structure list in this field.

LISTVER=listversion

Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSINFRM request to include equate (EQU) statements in your program for the CQSINFRM list versions.

PARM=parm address

Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSINFRM_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=return code address

Output parameter that specifies the address of a 4-byte field to contain the CQSINFRM return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

RSNCODE=reason code address

Output parameter that specifies the address of a 4-byte field to contain the CQSINFRM reason code.

Return and reason codes for CQSINFRM

The following table lists the return and reason code combinations that can be returned for CQSINFRM requests. Use a CQSINFRM FUNC=DSECT request to include equate statements in your program for the return and reason codes.

[CQS Client Structure Inform exit routine (Exit Routines)]

CQSMOVE request

A CQSMOVE request moves one or all client data objects from one queue to another. Data objects can be moved from the first or last position of the old queue to the first or last position on the new queue.

Format for CQSMOVE

_DSECT function of CQSMOVE_

You use the DSECT function of a CQSMOVE request to include equate (EQU) statements in your program for the CQSMOVE parameter list length, CQSMOVE return and reason codes, and literals that can be used to build the OPTWORD1 parameter.

►►CQSMOVE—FUNC=DSECT◄◄

_Move function of CQSMOVE_

Use the MOVE function of a CQSMOVE request to move one or all data objects from one queue to another. You must code a macro invocation for each combination of literal parameters.

_MOVE Function of CQSMOVE using Literal Parameters_

►►CQSMOVE—FUNC=MOVE—CQSTOKEN=cqstokenaddress—CONTOKEN=connecttokenaddress◄◄
You can use the OPTWORD1 parameter to code a single invocation of the macro and set the options at runtime. However, you cannot use the COUNT, NEWQPOS, and OLDQPOS parameters if you use the OPTWORD1 parameter.

**MOVE Function of CQSMOVE using OPTWORD1 Parameter**

Usage of CQSMOVE

**Restriction:** The CQSMOVE request is not supported for resource structures.

A CQSMOVE request moves one or all client data objects from one queue to another. Data objects can be moved from the first or last position of the old queue to the first or last position on the new queue. The client identifies the data objects to be moved either by the old queue name and queue position, or by the lock token. Do not move multiple objects with the same queue name and UOW; otherwise CQS cannot recover the objects.

If CQS or the client fails before CQS responds to the client, the CQSMOVE request might not complete. The client must reconnect to CQS after the failure and may have to issue the CQSMOVE request again, in case the failure occurred before the move was committed, or to resume a move with COUNT=ALL.

**Parameter Description:**
**CONTOKEN=connecttokenaddress**
Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client’s connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**COUNT=ONE | ALL**
Input parameter that specifies the number of data objects on the old queue to be moved; the client can move either one or all of them.

The COUNT parameter cannot be used when the OPTWORD1 parameter is specified. If you specify the OPTWORD1 parameter instead of the COUNT parameter, you can use the following equate (EQU) symbols to generate the value for the OPTWORD1 parameter:

```
CQSMOVE_CNTIEQUX COUNT=ONE
CQSMOVE_CNTLEQUX COUNT=ALL
```

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**
Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LCKTOKEN=locktokenaddress**
Input parameter that specifies the address of the 16-byte lock token for the locked data object to be moved. The lock token uniquely identifies a data object locked by a CQSREAD request.

**MVCNT=movecountaddress**
Output parameter that specifies the address of a 4-byte field to receive the number of data objects that were moved. Even when the return or reason code is non-zero, it is possible that CQS moved some data objects.

**NEWQ=newqueuenameaddress**
Input parameter that specifies the address of the 16-byte name of the new queue to which the data object is to be moved.

**NEWQPOS=FIRST | LAST**
Input parameter that specifies the position on the new queue to which data objects are moved, either first or last.

The NEWQPOS parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of NEWQPOS, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```
CQSMOVE_NEWQFEQUX NEWQPOS=FIRST
CQSMOVE_NEWQLEQUX NEWQPOS=LAST
```

**OLDQ=oldqueuenameaddress**
Input parameter that specifies the address of the 16-byte name of the old queue from which the data object is to be moved.

**OLDQPOS=FIRST | LAST**
Input parameter that specifies the position on the old queue from which data objects are to be moved, either first or last.
The OLDQPOS parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of OLDQPOS, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```
CQSMOVE_OLDQFEQUX OLDQPOS=FIRST
CQSMOVE_OLDQLEQUX OLDQPOS=LAST
```

**OPTWORD1=optionwordvalue**

Four-byte input parameter that specifies the literals for this request. This parameter can be used instead of COUNT, NEWQPOS, and OLDQPOS. Equate (EQU) statements for the literal values are listed under the COUNT, NEWQPOS, and OLDQPOS parameter descriptions. Equate statements can also be generated by using the DSECT function. The OPTWORD1 parameter cannot be used if COUNT, NEWQPOS, or OLDQPOS is specified.

**Requirement:** If you code the OPTWORD1 parameter, you must pass a value that is composed of one equate value for each literal value supported by this macro.

**PARM=parmaddress**

Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSMOVE_PARM_LEN (defined using the FUNC=DSECT request).

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSMOVE return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSMOVE reason code.

**Return and reason codes for CQSMOVE**

The following table lists the return and reason code combinations that can be returned for CQSMOVE requests. Use a CQSMOVE FUNC=DSECT request to include equate statements in your program for the return and reason codes.

### CQSPUT request

A CQSPUT request allows a client to place a data object on a queue. The data object can be either the only one for a unit of work, or it can be one in a series for a unit of work.

### Format for CQSPUT

#### ABORT function of CQSPUT

Use the ABORT function of a CQSPUT request to remove all uncommitted data objects from the queues that are associated with a recoverable unit of work.

```
CQSPUT FUNC=ABORT CQSTOKEN=cqstokenaddress CONTOKEN=connecttokenaddress
PARM=parmaddress PUTTOKEN=puttokenaddress ECB=ecbaddress
RETCODE=returncodeaddress RSNCODE=reasoncodeaddress
```

#### DSECT function of CQSPUT

Use the DSECT function of a CQSPUT request to include equate (EQU) statements in your program for the CQSPUT parameter list length, CQSPUT return and reason codes, and literals that can be used to build the OPTWORD1 parameter.

```
CQSPUT FUNC=DSECT
```

#### PUT function of CQSPUT

Use the PUT function of a CQSPUT request to place a data object on a queue.

```
CQSPUT FUNC=PUT CQSTOKEN=cqstokenaddress CONTOKEN=connecttokenaddress
```
A CQSPUT request allows a client to place a data object on a queue. The data object can be either the only one for a unit of work, or it can be one in a series for a unit of work. The data object can be added to the beginning or to the end of the queue. After the data object is on the queue, it is available to any client that has access to that queue.
You can put multiple objects on the same queue for unit of work. Do not move these objects (CQSMOVE request) or allow these objects to be moved to the overflow structure (CQSCONN request); otherwise, CQS cannot recover the objects.

If a unit of work consists of multiple data objects, and they are all on the same queue, then when CQS places the first data object on the queue, it notifies other clients that have registered interest in the queue, even though not all of the data objects for the UOW are on the queue yet and the UOW has not yet been committed.

**Recommendation:** To ensure that a client does not retrieve incomplete data, place the last data object for a UOW on a different queue than any of the previous data objects for the unit of work, and ensure the client only registers interest in that queue.

The first request that places a data object on a queue for a unit of work determines whether that unit of work is recoverable or nonrecoverable. The actions taken for a data object when a client fails, CQS fails, a structure is copied, or a structure is recovered depend on whether the unit of work is recoverable and, if so, whether it has been committed. The following table shows the actions taken for each case.

When a data object is put on a queue, a time stamp is stored with the data object. The source of the time stamp is based on whether TIMESTAMP= is used on the CQSPUT= request. If TIMESTAMP= is specified on the CQSPUT request, the value specified for TIMESTAMP= is stored with the data object. If TIMESTAMP= is not specified on the CQSPUT request, a time stamp representing the current time is generated and stored with the data object. The time stamp is returned on the CQSQUERY FUNC=QTYPE request if it is associated with the oldest data object on the queue or the newest data object on the queue.

**Table 15. Actions taken for data objects as a result of failures or structure activity**

<table>
<thead>
<tr>
<th></th>
<th>Nonrecoverable</th>
<th>Recoverable and uncommitted</th>
<th>Recoverable and committed</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client Failure</strong></td>
<td>All data objects on the queues for nonrecoverable units of work are left on the queues.</td>
<td>All data objects on the queues that belong to uncommitted units of work are deleted when the client terminates.</td>
<td>All data objects on the queues for the unit of work remain on the queues.</td>
</tr>
<tr>
<td><strong>CQS Failure</strong></td>
<td>Any data objects for nonrecoverable units of work that were placed on the queues successfully are left on the queues. If CQS was in the process of placing a data object on a queue when the failure occurred, that data object is not recovered when CQS restarts.</td>
<td>All data objects on the queues that belong to uncommitted units of work are deleted when CQS restarts.</td>
<td>All data objects on the queues that belong to committed units of work remain on the queues. If CQS was in the process of placing the final data object for the unit of work on the queues when the failure occurred, CQS restart ensures the data object is on the queues.</td>
</tr>
<tr>
<td><strong>Structure Copy</strong></td>
<td>Data objects for nonrecoverable units of work are copied to the new structure.</td>
<td>All data objects for recoverable units of work are copied to the new structure whether the unit of work is committed or not.</td>
<td>All data objects for recoverable units of work are copied to the new structure.</td>
</tr>
<tr>
<td><strong>Structure Recovery</strong></td>
<td>Data objects placed on the queues for nonrecoverable units of work are not recovered to the new structure.</td>
<td>All data objects that were placed on the queues for recoverable units of work are recovered to the new structure whether or not the unit of work was committed.</td>
<td>All data objects that were placed on the queues for recoverable units of work are recovered to the new structure.</td>
</tr>
</tbody>
</table>
A CQSPUT FUNC=FORGET request terminates any CQSPUT FUNC=PUT requests, and causes CQS to discard internal information CQS has about the unit of work. The unit of work is identified by the put token. The client should make this request after receiving a response from the final CQSPUT FUNC=PUT request issued for the unit of work. The CQSPUT FUNC=FORGET request is rejected if the unit of work is recoverable but not committed.

A CQSPUT FUNC=ABORT request removes from the queues all uncommitted data objects associated with a recoverable unit of work. The unit of work is identified by the put token. The request is rejected if the unit of work is nonrecoverable or if the unit of work is recoverable, but already committed.

Examples: To put a single object for a unit of work on the queues, issue the following requests:

CQSPUT FUNC=PUT,COMMIT=YES,...
;
CQSPUT FUNC=FORGET,...

To put multiple objects for a unit of work on the queues, issue the following requests:

CQSPUT FUNC=PUT,COMMIT=NO,...
;
CQSPUT FUNC=PUT,COMMIT=NO,...
;
CQSPUT FUNC=PUT,COMMIT=YES,...
;
CQSPUT FUNC=FORGET,...

Parameter description:

COMMIT= YES | NO
Input parameter that indicates whether to commit a recoverable unit of work. One or more data objects can be placed on the queues for a recoverable unit of work.

The COMMIT= parameter applies only to recoverable units of work and is only valid if RECOVERABLE=YES is specified. The parameter is ignored if RECOVERABLE=NO is specified.

COMMIT=YES must be specified (either by itself or as part of OPTWORD1) for the final (or only) CQSPUT FUNC=PUT request issued for a unit of work. If more than one data object is placed on the queues for a unit of work, COMMIT=NO must be specified on all except the final CQSPUT FUNC=PUT request of the series. COMMIT=YES must be specified on the final CQSPUT FUNC=PUT request.

The COMMIT parameter cannot be used if the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is used instead of COMMIT, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

CQSPUT_CMTYEQUX COMMIT=YES
CQSPUT_CMTNEQUX COMMIT=NO

CONTOKEN=connecttokenaddress
Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.
**CQSTOKEN=cqstokenaddress**

Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**DATAOBJ=dataobjectaddress**

A 4-byte input parameter that specifies the address of the client data object to be placed on the specified queue.

**ECB=ebaddress**

A 4-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise, it is processed synchronously.

**LOCAL=NO | N | YES | Y**

Input parameter that indicates whether the client should keep a local copy of the data.

**NO** Indicates the client wants CQS to place the data object on the specified client queue and make the object available to other CQSs.

**YES** Indicates that the client wants CQS to place the data object on the shared queues and to lock the object. LOCAL=YES also indicates that the client will keep a local copy of the data object in a local buffer.

By keeping a local copy of the data object, the client can reduce the performance impact of using shared queues. By keeping the data object on the shared queues, it can be recovered if the client fails. By locking the data object, it is not available to any other client.

The client must issue the CQSREAD LOCAL=YES request to process the data (retrieve the lock token for the data object and inform CQS that the client is processing the data). The data object is not returned to the client on a CQSREAD request because the client has the local copy. If the client does not issue the CQSREAD LOCAL=YES request and the connection between the client and CQS is lost, CQS unlocks the data object and makes it available to any client.

The LOCAL parameter cannot be used if the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is used instead of LOCAL, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```
CQSPUT_LCLYEQUX LOCAL=YES
CQSPUT_LCLNEQUX LOCAL=NO
```

**OBJSIZE=dataobjectsizedaddress**

Input parameter that specifies the address of a 4-byte area to hold the size of the client data object to be placed on the queue. The maximum size that can be specified is 61312 bytes (X'EF80').

**OPTWORD1=optionwordvalue**

A 4-byte input parameter that specifies the literals for this request. This parameter can be used instead of COMMIT, LOCAL, QPOS, and RECOVERABLE. Equate (EQU) statements for the literal values are listed under the descriptions of the COMMIT, LOCAL, QPOS, and RECOVERABLE parameters. Equate statements can be also generated by using the DSECT function. The OPTWORD1 parameter cannot be used if COMMIT, LOCAL, QPOS, or RECOVERABLE is specified.
Requirement: If you code the OPTWORD1 parameter, you must pass a value that is composed of one equate value for each literal value supported by this macro.

**PARM=parmaddress**
A 4-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSPUT_PARM_LEN (defined using the FUNC=DSECT request).

**PUTTOKEN=puttokenaddress**
A 4-byte input and output parameter that specifies the address of a 16-byte token to be used by CQS to relate a series of CQSPUT requests for a unit of work. The token must be zero for the initial CQSPUT request of a series. An updated token is returned by CQS for each CQSPUT request. The updated token must be returned to CQS on the next CQSPUT request for the unit of work. The *puttoken* must also be returned to CQS for any CQSPUT FUNC=FORGET or CQSPUT FUNC=ABORT requests.

**QNAME=queuenameaddress**
Input parameter that specifies the address of the 16-byte name of the queue on which the data object is to be placed. The first byte of the queue name cannot be zero because it is used to determine the queue type. If the value in the first byte is greater than the maximum number of queue types defined by CQS, it is folded into one of the existing queue types. If the last data object for a unit of work is being put on the structure, the data object must be put on a different queue than any of the previous data objects for that unit of work.

**QPOS=LAST | FIRST**
Input parameter that specifies the position on the queue at which to place the client data object.

- **FIRST**
  The data object is added to the beginning of the queue.

- **LAST**
  The data object is added to the end of the queue.

The QPOS parameter cannot be used if the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of QPOS, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```plaintext
CQSPUT_QPOSFEQUX  QPOS=FIRST
CQSPUT_QPOSLEQUX  QPOS=LAST
```

**RECOVERABLE=YES | NO**
Input parameter that specifies whether the unit of work is recoverable by CQS. RECOVERABLE=NO indicates that the unit of work is nonrecoverable. Only one data object can be placed on the queues for a nonrecoverable unit of work. RECOVERABLE=YES indicates that the unit of work is recoverable. One or more data objects can be placed on the queues for a recoverable unit of work.

The RECOVERABLE=YES parameter must be specified for each CQSPUT FUNC=PUT request issued for the unit of work. The unit of work is not committed until the final (or only) data object for the series is placed on the queues (COMMIT=YES specified).

The RECOVERABLE parameter cannot be used if the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of
RECOVERABLE, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

\[
\text{CQSPUT_RECVYEQUX RECOVERABLE=YES} \\
\text{CQSPUT_RECVNEQUX RECOVERABLE=NO}
\]

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSPUT return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSPUT reason code.

**TIMESTAMP=timestampaddress**

A 4-byte input parameter that specifies the address of an 8-byte STCK value that is stored with the data object as the time the data object was placed on the queue. If the TIMESTAMP parameter is omitted, the current time is stored with the data object.

**UOW=uowaddress**

Input parameter that specifies the address of a 32-byte area to hold the unit of work. This parameter is required for the initial (or only) CQSPUT FUNC=PUT request issued for a unit of work. It is ignored for all subsequent CQSPUT FUNC=PUT requests issued for that unit of work.

When a value is specified for the UOW= parameter, PUTTOKEN=0 must also be specified. The value specified for the UOW= parameter cannot be all zeroes, and must be unique within the shared queues. The client is responsible for ensuring that the value is unique.

### Return and reason codes for CQSPUT

The following table lists the return and reason code combinations that can be returned for CQSPUT requests. Use a CQSPUT FUNC=DSECT request to include equate statements in your program for the return and reason codes.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>

</table>

CQSQUERY request

The CQSQUERY request retrieves information or status about one or more of the structures managed by CQS.

Format for CQSQUERY

DSECT function of CQSQUERY

You use the DSECT function of a CQSQUERY request to include equate (EQU) statements in your program for the CQSQUERY parameter list length and CQSQUERY return and reason codes.

QNAME function of CQSQUERY

Use the QNAME function of a CQSQUERY request to retrieve information about a specific queue managed by CQS.
**QRYOBS function of CQSQUERY**

Use the QRYOBS function of a CQSQUERY request to retrieve the queue counts for a specified list of queue names.

```
CQSQUERY FUNC=QRYOBS CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress PARM=parmaddress COUNT=count
LIST=listaddress BUFFER=bufferaddress BUFSIZE=buffersize
QDATASZ=querydatasizeaddress ECB=ecbaddress RETCODE=returncodeaddress
-RSNCODE=reasoncodeaddress LISTVER=listversion
```

**QTYPE function of CQSQUERY**

Use the QTYPE function of a CQSQUERY request to retrieve information about all or some of the queues within the specified queue type.

```
CQSQUERY FUNC=QTYPE CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress PARM=parmaddress QTYPE=queuetypeaddress QTYPE=N=COLDQ
BUFFER=bufferaddress BUFSIZE=buffersize QAGE=queueagevalue
QDATASZ=querydatasizeaddress ECB=ecbaddress RETCODE=returncodeaddress
-RSNCODE=reasoncodeaddress LISTVER=listversion
```
**STATISTICS function of CQSQUERY**

Use the STATISTICS function of a CQSQUERY request to retrieve status information on all the queues managed by CQS.

- `CQSQUERY—FUNC=STATISTICS—CQSTOKEN=cqstokenaddress—PARM=parmaddress—COUNT=count—LIST=listaddress—BUFFER=bufferaddress—BUFSIZE=buffersize—STATSZAR=statisticssizeaddress—ECB=ecbaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress—LISTVER=listversion`

**STRSTAT function of CQSQUERY**

Use the STRSTAT function of the CQSQUERY request to retrieve structure related statistics. The STRSTAT function returns the same statistics data that is given to the Structure Statistics user exit routine.

**Attention:** If the CQS that is processing the request is in the middle of a structure checkpoint, the data returned for the current structure checkpoint might be incomplete.

- `CQSQUERY—FUNC=STRSTAT—CQSTOKEN=cqstokenaddress—CONTOKEN=connecttokenaddress—PARM=parmaddress—BUFSIZE=buffersize—QDATASZ=querydatasizeaddress—ECB=ecbaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress—LISTVER=listversion`

**Usage of CQSQUERY**

The CQSQUERY request retrieves information or status about one or more of the structures managed by CQS. A CQSQUERY FUNC=QNAME request retrieves information about one or more specific queues managed by CQS. A CQSQUERY FUNC=QRYOBJJS request retrieves the queue counts for one or more specific queues or queues whose names match a wildcard parameter. A CQSQUERY
FUNC=QTYPE request retrieves information about all or some of the queues within the specified queue type. A CQSQUERY FUNC=STATISTICS request retrieves status information for all queues managed by CQS. A CQSQUERY FUNC=STRSTAT request retrieves structure statistics, such as checkpoint and rebuild, without having to code a user exit.

**Restriction:** The CQSQUERY FUNC=QNAME, CQSQUERY FUNC=QRYOBJJS, and CQSQUERY FUNC=QTYPE requests are not supported for resource structures.

**CQSQUERY FUNC=QNAME**

For CQSQUERY FUNC=QNAME, the number of data objects for the *queue name* specified in LIST= is returned.

If the QAGE parameter is specified, only information for queues older than the specified queue age is returned. If you are only interested in queue counts, you can omit the QAGE parameter for better performance of the CQSQUERY request.

**CQSQUERY FUNC=QRYOBJJS**

For CQSQUERY FUNC=QRYOBJJS, the number of data objects for the *queue name* specified in LIST= is returned. Each queue name in the list can be up to 16 bytes long. The first byte of the qname is treated as the QTYPE. The input list for each qname also has 8 bytes of user data that are copied to the output for each entry that is a match for the input queue name.

The CQSQUERY FUNC=QRYOBJJS output is returned both in the input list and the output buffer. The input list has the completion code for the queue name. If the completion code is 0, then the queue names that match the input queue name and their queue counts are returned in the output buffer. If the completion code is non-zero, no data is passed for that queue name in the output buffer. The input list has the total queue count found for the queue name. If the queue name is a wildcard parameter, this queue count is the total queue counts of all the queue names that match the wildcard parameter. An entry for each queue name that is a match is passed in the output buffer along with the queue count for the queue name. If the buffer size specified is too small, the data that fits in the buffer is passed back, and the actual length required is passed back in the QDATASZ field.

**Recommendation:** Use the CQSQUERY FUNC=QRYOBJJS request carefully, because it causes CQS to read every data object on the queue type, and thus could have a significant performance impact.

**CQSQUERY FUNC=QTYPE**

For CQSQUERY FUNC=QTYPE, information about all the queues in the queue type is returned, including the queue name, data object count, oldest data object time stamp, and newest data object time stamp.

**Recommendation:** Use the CQSQUERY FUNC=QTYPE request carefully, because it causes CQS to read every data object on the queue type, and thus could have a significant performance impact.

For CQSQUERY FUNC=QTYPE, CQS does the following if the buffer area is not large enough to hold all of the requested data:

- Returns as many complete records that can fit into the buffer area
• Sets QDATASZ to the length that is needed to contain the statistics data in its entirety
• Sets the reason code for 'Partial Data Returned'

The client program can then make another request with a larger buffer.

**CQSQUERY FUNC=STATISTICS**

For CQSQUERY FUNC=STATISTICS, CQS returns the following information in the client buffer:

- Status on the current capacity of the primary structure
- Maximum capacity of the primary structure (if XES dynamic reconfiguration is available)
- Current operation mode (normal, overflow, or rebuild)
- Elements-to-entries ratio (returned in the buffer passed by the client for this request)

If an overflow structure is defined and the current operation mode for the primary structure is overflow mode, CQS also returns the current and maximum capacity for the associated overflow structure. If the primary structure is not in overflow mode and an overflow structure is defined, CQS returns the overflow structure name and a status indicating that the overflow structure is not in use.

If the buffer area is not large enough to contain the statistics data for all of the requested structures, CQSQUERY FUNC=STATISTICS sets theSTATSZAR field to be the length of a single statistics entry, and sets the reason code to 'Buffer Size Too Small.' The size of the buffer that is required to complete the request can be obtained by multiplying the value returned in STATSZAR by the number of list entries specified in the request.

**CQSQUERY FUNC=STRSTAT**

For CQSQUERY FUNC=STRSTAT, CQS returns the following information:

- Structure process statistics
- CQS request statistics
- Data object statistics
- Queue name statistics
- z/OS request statistics
- Structure rebuild statistics
- Structure checkpoint statistics

For this function, CQS does the following if the buffer area is not large enough to hold all of the requested data: The client program can then make another request with a larger buffer:

- Returns as many complete records that can fit into the buffer area
- Sets QDATASZ to the length that is needed to contain the statistics data in its entirety
- Sets the reason code for 'Partial Data Returned'

The following keywords apply to the CQSQUERY macro. Note that some of the information provided here applies to specific CQSQUERY functions.
**BUFFER=bufferaddress**

Four-byte input parameter that specifies the address of the buffer to hold information passed to the client.

For CQSQUERY FUNC=QTYPE, the buffer is mapped by the CQSQRYQT DSECT. For CQSQUERY FUNC=STATISTICS, the buffer is mapped by the CQSQRYST DSECT. For CQSQUERY FUNC=STRSTAT, the buffer is mapped by the CQSQSTAT DSECT. For CQSQUERY FUNC=QRYOBJS, the buffer is mapped by the CQSQRYQO DSECT.

**BUFSIZE=buffersize**

Four-byte input parameter that specifies the size of the buffer passed by the client.

**CONTOKEN=connecttokenaddress**

Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**COUNT=count**

Four-byte input parameter that specifies the number of entries in the list.

**CQSTOKEN=cqstokenaddress**

Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**

Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LIST=listaddress**

Four-byte input parameter that specifies the address of a list containing one or more entries. For the CQSQUERY FUNC=QNAME and CQSQUERY FUNC=QRYOBJS requests, this list contains queue names for which to retrieve information. The list consists of input and output parameters. At least one list item is required.

The CQSQRYL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

For a CQSQUERY FUNC=QNAME request, each list entry contains the following:

**compcode**

Four-byte output field to receive the completion code from the request. Possible completion codes are:

- X'00000000'
  
  Request completed successfully.

- X'00000004'
  
  queue name is invalid.

- X'00000020'
  
  Structure is inaccessible. Retry request.

- X'00000024'
  
  CQS internal error.
clientdata
Eight-byte input parameter that specifies the client data field. This parameter is optional. CQS does not use data stored in this entry.

queuename
Sixteen-byte input parameter that specifies the queue name for which data object count information is to be retrieved. This parameter is required.

qcnt
Four-byte output parameter that specifies a field to contain the data object count for the queue name specified.

For a CQSQUERY FUNC=STATISTICS request, each list entry contains the following parameters:

comppcode
Four-byte output field to receive the completion code from the request. Possible completion codes are:

X'00000000'
   Request completed successfully.

X'00000008'
   connecttoken is invalid.

X'0000000C'
   A CQSRSYNC is required for this structure.

X'00000020'
   Structure is inaccessible. Retry request.

X'00000024'
   CQS internal error.

clientdata
Eight-byte input parameter that specifies the client data field. This parameter is optional. CQS does not use data stored in this entry.

connecttoken
Sixteen-byte input parameter that specifies the connect token that uniquely identifies the client’s connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request. This parameter is required.

outputoffset
Four-byte output parameter that specifies the offset of the output data area for this entry in the output buffer.

For a CQSQUERY FUNC=QRYOBJS request, each list entry contains the following parameters:

comppcode
Four-byte output field to receive the completion code from the request. Possible completion codes are:

X'0000'
   Request completed successfully. A list of resources that match the qname and their queue counts are returned in the output buffer.

X'0004'
   qname is invalid.
X'0010'
qname does not have any objects. The queue count is zero.

X'0020'
Retry error for the qname. Retry the CQSQUERY FUNC=QRYOJBJS to obtain the queue counts. The output returned in the output buffer might be invalid.

X'0024'
CQS internal error. Retry the CQSQUERY FUNC=QRYOJBJS to obtain the queue counts. The output returned in the output buffer might be invalid.

clientdata
Eight-byte input parameter that specifies the client data field. This parameter is optional. CQS does not use data stored in this entry.

queuename
Sixteen-byte input parameter that specifies the queue name for which data object count information is to be retrieved. This parameter is required. The queuename can be a wildcard parameter.

qcnt
Four-byte output parameter that specifies a field to contain the data object count for the queue name specified. If the queuename is a wildcard parameter, this parameter specifies a field to contain the total queue counts of all qnames that match the wildcard parameter.

LISTVER=1 | listversion
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSQUERY request to include equate (EQU) statements in your program for the CQSQUERY list versions.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSQUERY_PARM_LEN (defined using the FUNC=DSECT request).

QAGE=queueageaddress
Input parameter that specifies the address of a 4-byte field to contain the queue age in days. Valid values for queueage are from X'0' to X'16D' (0 to 365 in decimal).

Definition: The queue age is determined by the age of its oldest message, in number of days.

This parameter is used as a filter for determining which queues the CQSQUERY FUNC=QTYPE request will process. The CQSQUERY request returns information for queues containing data objects that are older than the specified queueage. If you specify 0 for queueage, or omit the QAGE parameter, the CQSQUERY request processes all queues for the queue type.

Important: Specifying QAGE causes all the data objects in the queue to be read, which incurs additional performance overhead.

QDATASZ=querydatasizeaddress
Output parameter that specifies the address of a 4-byte field to contain the size of the information returned to the client. If partial data is returned in the buffer, this field contains the actual buffer size needed to hold the information.
**QTYPE=queuetypeaddress**

Input parameter that specifies the address of a 4-byte field that contains the queue type. Valid values for the queue type are from 1 to 255 (decimal).

**QTPENM=COLDQ**

Input parameter that indicates that the CQSQUERY request is for information about the COLDQ.

This parameter enables a client to obtain the same type of information for the cold queue as can be obtained for a client queue using the CQSQUERY FUNC=QTYPE request with QTYPE=queuetypeaddress specified.

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSQUERY return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSQUERY reason code.

**STATSZAR=statisticssizeaddress**

Output parameter that specifies the address of a 4-byte field to contain the length of a single statistics entry returned in the output buffer for a CQSQUERY FUNC=STATISTICS request.

If partial data is returned, the size of the required buffer can be obtained by multiplying the value returned in this field by the number of list entries specified.

**Return and reason codes for CQSQUERY**

The following table lists the return and reason code combinations that can be returned for CQSQUERY requests. Use a CQSQUERY FUNC=DSECT request to include equate statements in your program for the return and reason codes.

*Table 17. CQSQUERY return and reason codes*

<table>
<thead>
<tr>

CQSREAD request

The CQSREAD request retrieves a copy of the client data object from a specific queue.

Format for CQSREAD

CONTINUE function of CQSREAD

You use the CONTINUE function of a CQSREAD request to retrieve the rest of a data object after partial data is returned for a prior CQSREAD request.

►►CQSREAD—FUNC=CONTINUE—CQSTOKEN=cqstokenaddress

►CONTOKEN=connecttokenaddress—PARM=parmaddress—LCKTOKEN=locktokenaddress

►BUFFER=bufferaddress—BUFSIZE=buffersize—OBJSIZE=dataobjectsizexadress

►ECB=ecbaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress

DSECT function of CQSREAD

Use the DSECT function of a CQSREAD request to include equate (EQU) statements in your program for the CQSREAD parameter list length, CQSREAD return and reason codes, and literals that can be used to build the OPTWORD1 parameter.

►►CQSREAD—FUNC=DSECT

READ function of CQSREAD with LOCAL=NO
Use the CQSREAD request with the LOCAL=NO parameter to retrieve a copy of the client data object from a specific queue and lock it.

```
CQSREAD FUNC=READ CQSTOKEN=cqstokenaddress CONTOKEN=connecttokenaddress
PARM=parmaddress LCKTOKEN=locktokenaddress QNAME=queueaddress
OBJSIZE=dataobjectsizeaddress UOW=uowaddress

OPTWORD1=optionwordvalue BUFFER=bufferaddress BUFSIZE=buffersize
TIMESTAMP=timestampaddress ECB=ecbaddress
RETCODE=returncodeaddress RSNCODE=reasoncodeaddress
```

A:

```
QPOS=FIRST QPOST=LAST
PARTIAL=YES LOCAL=NO
```

**READ function of CQSREAD with LOCAL=YES**

Use the CQSREAD request with the LOCAL=YES parameter to retrieve the lock token of a data object previously stored on the shared queues by a CQSPUT LOCAL=YES request. Using this request ensures that the data object remains locked, even in the event of client failure, structure rebuild, or CQS restart.

```
CQSREAD FUNC=READ CQSTOKEN=cqstokenaddress CONTOKEN=connecttokenaddress
PARM=parmaddress LCKTOKEN=locktokenaddress QNAME=queueaddress
UOW=uowaddress LOCAL=YES

OPTWORD1=optionwordvalue ECB=ecbaddress
RETCODE=returncodeaddress RSNCODE=reasoncodeaddress
```

**REREAD function of CQSREAD**

Use the REREAD function of a CQSREAD request to re-read a locked data object that was read and locked on a prior CQSREAD FUNC=READ request.

```
CQSREAD FUNC=REREAD CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress PARM=parmaddress LCKTOKEN=locktokenaddress
```

Chapter 2. CQS client requests
Usage of CQSREAD

A CQSREAD request retrieves a copy of the client data object from a specific queue. The data object is not deleted from the queue, but for a CQSREAD FUNC=READ request it is locked, preventing the data object from being accessed by subsequent CQS requests (except ones using the proper lock token). The data object can be retrieved from the beginning or from the end of the queue. The data object is returned in the client buffer provided for the CQSREAD request.

Restriction: The CQSREAD request is not supported for resource structures.

A lock token is returned to the client and identifies the data object. This token must be passed to CQS for any requests that act on the locked data object (for example, CQSDEL, CQSMOVE, CQSREAD, or CQSUNLCK).

If the size of the data object retrieved is greater than the size of the client buffer and PARTIAL=YES is specified, the amount of data that fits in the client buffer is returned to the client. A return or reason code is also returned, indicating a partial data object is returned, as is the actual data object size.

If the size of the data object retrieved is greater than the size of the client buffer and PARTIAL=NO is specified, no data object is returned. A return and reason code is returned, indicating that no data object is returned because the client buffer size is too small. The actual data object size is also returned to the client.

If the size of the data object retrieved is the same size as or smaller than the client buffer, the complete data object is moved into the buffer, and the rest of the buffer is not changed. The data object size is also returned to the client.

A CQSREAD FUNC=CONTINUE request retrieves the rest of the data object when partial data is returned on a prior CQSREAD request.

Attention: This request could result in an error after a CQS restart because the current position might be lost across CQS restart.

A CQSREAD FUNC=REREAD request re-reads a locked data object that was previously read and locked (a prior CQSREAD FUNC=READ request). The data object remains locked.

Related reading: See the following example of how to use a CQSREAD request for a CQS client.

Parameter Description:

BUFFER=bufferaddress
  Four-byte input parameter that specifies the address of the client buffer that will hold the data object retrieved from the queue.

BUFSIZE=buffersize
  Four-byte input parameter that specifies the size of the client buffer.
**CONTOKEN=connecttokenaddress**

Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**CQSTOKEN=cqstokenaddress**

Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**

Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LCKTOKEN=locktokenaddress**

Input and output parameter that specifies the address of the 16-byte lock token for the data object that was locked by the CQSREAD request.

For a CQSREAD FUNC=READ request, the lock token is zero on input. It is also used as an output area to hold the lock token returned to the client. For a CQSREAD FUNC=REREAD or FUNC=CONTINUE request, this field is an input area that contains the lock token returned on a prior CQSREAD request.

**LOCAL=NO | YES**

Input parameter that indicates whether or not the client should process a local copy of the data object from the client address space.

NO Indicates the client wants CQS to return the data object from the specified client queue and lock the data object. This causes CQS to access the coupling facility to retrieve the data object.

YES Indicates that the client is processing a local copy of a data object from its local buffers. This request returns the lock token of the data object which the client can use to access the copy of the data object on the shared queues. The data object was placed on the shared queues by a CQSPUT LOCAL=YES request.

By using a local copy of the data object, the client can reduce the performance overhead of using shared queues. As long as the data object is on the shared queues, it can be recovered if the client fails. As long as the data object remains locked, it is not available to any other client.

The data object is not returned to the client on a CQSREAD request because the client has the local copy. If the client does not issue the CQSREAD LOCAL=YES request and the connection between the client and CQS is lost, CQS unlocks the data object and makes it available to any other client.

**Restriction:** If you specify LOCAL=YES, you cannot use the TIMESTAMP parameter.

The LOCAL parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of LOCAL, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```
CQSREAD_LCLYEQUX LOCAL=YES
CQSREAD_LCLNEQUX LOCAL=NO
```
OBJSIZE=dataobjectsizeaddress
Output parameter to receive the address of a 4-byte field that holds the size of the data object. If the data object size is greater than the client buffer size, this field contains the actual data object size. If partial data is returned, the size of the data object returned is the size of the client buffer specified.

OPTWORD1=optionwordvalue
Four-byte input parameter that specifies the literals for this request. This parameter can be used instead of LOCAL, PARTIAL, and QPOS. Equate (EQU) statements for the literal values are listed in the descriptions for the LOCAL, PARTIAL, and QPOS parameters. Equate statements can also be generated by using the DSECT function. The OPTWORD1 parameter cannot be used if LOCAL, PARTIAL, or QPOS is specified.

Requirement: If you code the OPTWORD1 parameter, you must pass a value that is composed of one equate value for each literal value supported by this macro.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSREAD_PARM_LEN (defined using the FUNC=DSECT request).

PARTIAL=YES | NO
Input parameter that specifies whether partial data is to be retrieved, and whether the data object is to be locked if the data object size is greater than the client buffer size.

YES
If the data object size is greater than the client buffer size, the data object is locked and partial data is returned in the client buffer. The actual size of the data object is returned in dataobjectsize.

NO
If the data object size is greater than the client buffer size, the data object is neither locked nor retrieved. The actual size of the data object is returned in dataobjectsize.

The PARTIAL parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of PARTIAL, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

CQSREAD_PRTLNEQX PARTIAL=NO
CQSREAD_PRTLYEQX PARTIAL=YES

QNAME=queueunameaddress
Input parameter that specifies the address of the 16-byte queue name from which the data object is to be retrieved. The first byte of the queue name identifies the queue type.

QPOS=FIRST | LAST
Input parameter that specifies the position on the queue from which the data object is to be retrieved.

FIRST
The data object is retrieved from the beginning of the queue.

LAST
The data object is retrieved from the end of the queue.
The QPOS parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of QPOS, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

- **CQSREAD_QPOSLEQUX**  QPOS=LAST
- **CQSREAD_QPOSFEQUX**  QPOS=FIRST

**RETCODE=returncodeaddress**
Output parameter that specifies the address of a 4-byte field to contain the CQSREAD return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**
Output parameter that specifies the address of a 4-byte field to contain the CQSREAD reason code.

**TIMESTAMP=timestampaddress**
Four-byte output parameter that specifies the address of an eight-byte field to contain the time stamp of when the data object was placed on the queues.

**Attention:** If LOCAL=YES is specified, CQS does not read the data object from the structure, and the time stamp cannot be obtained.

**UOW=uowaddress**
Output parameter that specifies the address of a 32-byte area to hold the unit of work (UOW) of the data object retrieved from the queue. The UOW was generated by the client that put the data object on the queue using a CQSPUT request.

### Return and reason codes for CQSREAD

The following table lists the return and reason code combinations that can be returned for CQSREAD requests. Use a CQSREAD FUNC=DSECT request to include equate statements in your program for the return and reason codes.

<table>

CQSRECVR request

The CQSRECVR request allows a client to recover locked data objects that were moved to the CQS cold queue (a CQS private queue) because CQS or the client was cold started.

Format for CQSRECVR

DELETE function of CQSRECVR

Use the DELETE function of a CQSRECVR request to delete one data object associated with a UOW from the cold queue.

```plaintext
►►CQSRECVR—FUNC=DELETE—CQSTOKEN=cqstokenaddress—CONTOKEN=connecttokenaddress—PARM=parmaddress—CLDTOKEN=coldqueuetokenaddress—UOW=uowaddressaddress—ECB=ecbaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress◄◄
```

DSECT function of CQSRECVR

Use the DSECT function of a CQSRECVR request to include equate (EQU) statements in your program for the CQSRECVR parameter list length, CQSRECVR return and reason codes, and literals that can be used to build the OPTWORD1 parameter.
**RETRIEVE function of CQSRECVR**

Use the RETRIEVE function of a CQSRECVR request to retrieve a copy of a data object associated with a UOW from the cold queue.

```
CQSRECVR FUNC=RETRIEVE
CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress
PARM=parmaddress
CLDTOKEN=coldqueuetokenaddress
UOW=uowaddress
BUFFER=bufferaddress
BUFSIZE=buffersize
OBJSIZE=dataobjectsizeaddress
ECB=ecbaddress
RETCODE=returncodeaddress
RSNCODE=reasoncodeaddress
```

**UNLOCK function of CQSRECVR**

Use the UNLOCK function of a CQSRECVR request to unlock a data object associated with a UOW on the cold queue.

```
CQSRECVR FUNC=UNLOCK
CQSTOKEN=cqstokenaddress
CONTOKEN=connecttokenaddress
PARM=parmaddress
CLDTOKEN=coldqueuetokenaddress
UOW=uowaddress
OPTWORD1=optionwordvalue
ECB=ecbaddress
RETCODE=returncodeaddress
RSNCODE=reasoncodeaddress
```

**Usage of CQSRECVR**

**Restriction:** The CQSRECVR request is not supported for resource structures.

A CQSRECVR FUNC=DELETE request deletes a data object associated with a UOW from the cold queue. Only one data object is deleted.

A CQSRECVR FUNC=RETRIEVE request retrieves a copy of the data object associated with a UOW from the cold queue. The data object remains on the cold
queue, and is available for other CQSRECVR requests. The data object is returned in the client buffer specified for the CQSRECVR FUNC=RETRIEVE request.

If the data object is the same size as or smaller than the client buffer provided, the data object is returned in the buffer, and the rest of the buffer is not changed. The size of the data object is returned to the client.

If the size of the data object is greater than the size of the client buffer, the data object is not returned. The size of the data object is returned to the client.

A CQSRECVR FUNC=UNLOCK request unlocks a data object associated with a UOW on the cold queue. The data object is moved from the cold queue to the original client queue, and is available for other CQS requests. The position to which the data object should be moved can be specified by the client.

Parameter Description:

**BUFFER=bufferaddress**

Four-byte input parameter that specifies the address of the client buffer that will hold the data object retrieved from the queue.

**BUFSIZE=buffersize**

Four-byte input parameter that specifies the size of the client buffer.

**CLDTOKEN=coldqueuetokenaddress**

Input parameter that specifies the address of a 16-byte cold-queue token, which along with the UOW identifies the data object that is to be recovered from the CQS cold queue (COLDQ).

The cold-queue token is passed to the client in the SEVX_RETOKEN field of the Resync entry in the CQS Structure Event exit routine. This exit routine is called for a CQS-initiated resynchronization when the UOW status is COLD.

**CONTOKEN=connecttokenaddress**

Input parameter that specifies the address of a 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**CQSTOKEN=cqstokenaddress**

Input parameter that specifies address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**

Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**OBJSIZE=dataobjectsizeofaddress**

Output parameter that specifies the address of a 4-byte area to hold the size of the data object. If the data object size is greater than the client buffer size, this field contains the actual data object size. If partial data is returned, the data object returned is the size of the client buffer specified.

**OPTWORD1=optionwordvalue**

Four-byte input parameter that specifies the literals for this request. This parameter can be used instead of QPOS. Equate (EQU) statements for the literal values are listed in the description of the QPOS parameter. Equate
statements can also be generated by using the DSECT function. The OPTWORD1 parameter cannot be used if QPOS is specified.

**Requirement**: If you code the OPTWORD1 parameter, you must pass a value that is composed of one equate value for each literal value supported by this macro.

**PARM=parmaddress**

Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSRECVR_PARM_LEN (defined using the FUNC=DSECT request).

**QPOS=SYSTEM | FIRST | LAST**

Input parameter that specifies the position on the queue to which the unlocked data object is to be added. The default is SYSTEM.

**FIRST**

Indicates the data object is unlocked and added to the beginning of the queue.

**LAST**

Indicates the data object is unlocked and added to the end of the queue.

**SYSTEM**

Indicates the data object is unlocked and added to either the beginning or the end of the queue, depending on its original position. If the CQSREAD request that locked this data object obtained the data object from the beginning of the queue, the data object is unlocked and added to the beginning of the queue. If the CQSREAD request obtained the data object from the end of the queue, the data object is unlocked and added to the end of the queue.

The QPOS parameter cannot be used when the OPTWORD1 parameter is specified. If the OPTWORD1 parameter is specified instead of QPOS, you can use the following equate (EQU) statements to generate the value for the OPTWORD1 parameter:

```
CQSRECVR_QPOSSEQUX QPOS=SYSTEM
CQSRECVR_QPOSFEQUX QPOS=FIRST
CQSRECVR_QPOSLEQUX QPOS=LAST
```

**RETCODE=returncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSRECVR return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**

Output parameter that specifies the address of a 4-byte field to contain the CQSRECVR reason code.

**UOW=uowaddress**

Input parameter that specifies the address of a 32-byte area to hold the unit of work (UOW) of a data object. The UOW, together with the coldqueuetoken, identifies the data object to be recovered from the cold queue.

The UOW is passed to the client in the SEVX_REUOW field of the Resync entry in the CQS Structure Event exit routine. This exit routine is called for a CQS-initiated resynchronization when the UOW status is COLD.
Return and reason codes for CQSRECVR

The following table shows the return and reason code combinations that can be returned for CQSRECVR requests. Use a CQSRECVR FUNC=DSECT request to include equate statements in your program for the return and reason codes.

CQSREG request

The CQSREG request registers a client to CQS.

Format for CQSREG

DSECT function of CQSREG

You use the DSECT function of a CQSREG request to include equate (EQU) statements in your program for the CQSREG parameter list length and CQSREG return and reason codes.

►►CQSREG—FUNC=DSECT—►◄

Use the REGISTER function of a CQSREG request to register a client with a CQS.

►►CQSREG—FUNC=REGISTER—PARM=parmaddress—CQSSN=cqssubsystemnameaddress—►
Usage of CQSREG

A CQSREG request registers a client to CQS. If the registration is successful, a CQS token is returned. This token represents the client's registration with CQS and must be used with all subsequent CQS requests to identify the client.

A CQSREG FUNC=REGISTER request must be the first CQS request a client makes. Also, after a CQS abnormal termination and restart, a CQSREG FUNC=REGISTER request is required before the client can resume issuing CQS requests.

CLIENT=clientnameaddress
Input parameter that specifies the address of the 8-byte name of the client registering to CQS. The client name must be unique among all clients that are registered to the same CQS and to all the CQSs that are sharing the same queues.

CQSTOKEN=cqstokenaddress
Output parameter that specifies the address of a 16-byte area to receive the CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by a successful CQSREG request.

CQSSSN=cqssubsystemnameaddress
Input parameter that specifies the address of the 4-byte subsystem name of the CQS to which the client would like to connect. This parameter should match the SSN= parameter of the CQSIPxxx PROCLIB member for the CQS to which the client would like to connect.

EVENT=cqseventexit
Four-byte input parameter that specifies the CQS Event exit routine address.

EVENTPARM=eventparmaddress
Input parameter that specifies the address of a 4-byte area that contains client data that CQS passes to the CQS Event exit routine every time the exit is called.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSREG_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSREG return code. The CQSREG return code is returned both in this field and in register 15.

RSNCODE=reasoncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSREG reason code. The CQSREG reason code is returned both in this field and in register 0.
**VERSION=cqsversionaddress**

Output parameter that specifies the address of a 4-byte area to receive the CQS version number. The version number has the following format: 00vvrrmm.

- **00**: This byte is reserved for future use. Currently, it is always 00.
- **vv**: Version number.
- **rr**: Release number.
- **mm**: Modification level or sub-release number.

For example, CQS version 1.1.0 is shown as X'00010100'.

**Return and reason codes for CQSREG**

The following table lists the return and reason code combinations that can be returned for CQSREG requests.

CQSRSYNC request

A CQSRSYNC request allows a client to resynchronize indoubt data for one structure with CQS. This request must be the first request the client issues following a CQSCONN request.

Format for CQSRSYNC

DSECT function of CQSRSYNC

You use the DSECT function of a CQSRSYNC request to include equate (EQU) statements in your program for the CQSRSYNC parameter list length and CQSRSYNC return and reason codes.

<table>
<thead>
<tr>
<th>CQSRSYNC—FUNC=DSECT</th>
</tr>
</thead>
</table>

RSYNCCOLD function of CQSRSYNC

Use the RSYNCCOLD function of a CQSRSYNC request when the client is performing a cold start and does not have information on unresolved UOWs.

<table>
<thead>
<tr>
<th>CQSRSYNC—FUNC=RSYNCCOLD—CQSTOKEN=cqstokenaddress</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTOKEN=connecttokenaddress—PARM=parmaddress—ECB=ecbaddress</td>
</tr>
<tr>
<td>RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress</td>
</tr>
<tr>
<td>LISTVER=1 — LISTVER=listversion</td>
</tr>
</tbody>
</table>

RSYNCWARM function of CQSRSYNC

Use the RSYNCWARM function of a CQSRSYNC request when the client is performing a warm or emergency restart and has information on unresolved UOWs that need to be resolved with CQS.

| CQSRSYNC—FUNC=RSYNCWARM—CQSTOKEN=cqstokenaddress |
Usage of CQSRSYNC

A CQSRSYNC request allows a client to resynchronize indoubt data for one structure with CQS. This request must be the first request the client issues following a CQSCONN request.

**Restriction:** The CQSRSYNC request is not supported for resource structures.

A CQSRSYNC request is required even if the client does not have any indoubt units of work (UOWs) to resolve, for example when the client performs a cold start or a warm start after a normal termination. This request is required because CQS might have information about a connection and have unresolved UOWs to process.

If there are unresolved UOWs, CQS calls the client’s Structure Event exit routine as part of resynchronization. CQS calls the routine to inform the client of UOWs that CQS knows about and that the client did not pass on the CQSRSYNC request. This process is referred to as CQS-initiated resynchronization.

The exit routine is called during client cold start or restart only if CQS has unresolved UOWs. The Structure Event exit routine can be called more than once for CQS-initiated resynchronization. For each UOW passed to the exit routine, the client is responsible for taking the correct action to resolve the UOW based on the status returned by CQS.

If CQS cold started, CQS has no knowledge of client UOWs. In this case, the resynchronization list is not processed. CQS looks for CQSREAD requests that were incomplete at the time CQS terminated. If there is incomplete work, the data objects are moved to the cold queue and the Structure Event exit routine is called to inform the client of the unresolved UOWs for the data objects.

After the CQSRSYNC request completes, some UOWs might have a deferred resynchronization status. This status indicates that CQS is still resynchronizing the UOW. When CQS completes resynchronization, the Structure Event exit routine is called to indicate the state of the UOW. Deferred resynchronization only applies to UOWs that CQS cannot resynchronize during the CQSRSYNC request, and does not occur for a client cold start. The exit routine is called once for each deferred UOW, and so the exit routine can be called multiple times for deferred resynchronization.

**Parameter Description:**

**CONTOKEN=connecttokenaddress**

Input parameter that specifies the address of the 16-byte connect token that
uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**COUNT=** count

Four-byte input parameter that specifies the number of entries in the resync list.

**CQSTOKEN=** cqstokenaddress

Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

**ECB=** ecbaddress

Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise it is processed synchronously.

**LIST=** listaddress

Four-byte input parameter that specifies the address of the resync list. Each entry contains an indoubt UOW that the client needs to resolve. Some fields in each entry must be initialized by the client prior to the CQSRSYNC request. Other fields are returned by CQS upon completion of the CQSRSYNC request.

The CQSRSYNL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following:

- **clientdata**
  
  Four-byte input parameter that specifies the client data field. This parameter is optional. CQS does not use data stored in this entry.

- **uow**
  
  Thirty-two-byte input parameter that specifies the unit of work identifier for the queue. This parameter is required and must be initialized by the client prior to the CQSRSYNC request.

- **clientstatus**
  
  Two-byte input parameter that contains the status of the UOW. This status represents the last action the client performed for this UOW. This parameter is required and must be initialized by the client prior to the CQSRSYNC request.

Possible values for the status are shown in the following table.

*Table 21. UOW status from the client*

</tr>
<tr>
<td></td>
<td>Client status is any valid client status. The UOW is unknown to CQS.</td>
</tr>
<tr>
<td></td>
<td>If the client believes the UOW to be in PUT Complete status, the client must determine whether or not to reissue the CQSPUT request.</td>
</tr>
<tr>
<td></td>
<td>If the client believes the UOW to have a status of Delete, Move, Read, or Unlock, the prior request could have completed.</td>
</tr>
</tbody>
</table>

resynctoken

Sixteen-byte output parameter to receive a token that the client uses to complete processing for the UOW. When the state is Put Insync, this field contains the put token. When the state is Locked, this field contains the lock token. This field is returned by CQS as a result of the CQSRSYNC request.

compcode

Four-byte output field to receive the completion code from the request. Possible completion codes are:

X'00000000'

CQS successfully processed this UOW. Client and CQS are in sync for this UOW. An Insync state is returned for this UOW.

X'00000004'

CQS successfully processed this UOW. Client and CQS are not in sync for this UOW. CQS returns its known state for this UOW.

X'00000008'

clientstatus is invalid. CQS could not resynchronize this UOW. The cqsstate is not returned.

X'0000000C'

uow is invalid. CQS could not resynchronize this UOW. The cqsstate is not returned.

X'00000010'

CQS internal error. CQS could not resynchronize this UOW. The cqsstate is not returned.
LISTVER=1 | listversion
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSRSYNC request to include equate (EQU) statements in your program for the CQSRSYNC list versions.

PARM=parmaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSRSYNC_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSRSYNC return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

RSNCODE=reasoncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSRSYNC reason code.

Return and reason codes for CQSRSYNC

The following table lists the return and reason code combinations that can be returned for CQSRSYNC requests. Use a CQSRSYNC FUNC=DSECT request to include equate statements in your program for the return and reason codes.

**CQSSHUT request**

A CQSSHUT request notifies CQS to terminate after all clients have disconnected.

**Format for CQSSHUT**

*DSECT function of CQSSHUT*

You use the DSECT function of a CQSSHUT request to include equate (EQU) statements in your program for the CQSSHUT parameter list length and CQSSHUT return and reason codes.

```
CQSSHUT—FUNC=DSECT
```

*QUIESCE function of CQSSHUT*

Use the QUIESCE function of a CQSSHUT request to terminate CQS.

```
CQSSHUT—FUNC=QUIESCE—CQSTOKEN=cqstokenaddress—PARM=parmaddress
```
Usage of CQSSHUT

A CQSSHUT request notifies CQS to terminate after all clients have disconnected. After the CQSSHUT request is issued, CQS stops accepting CQSCONN requests. CQS continues to accept input or output requests, so that clients can complete work in progress. In order to complete the shutdown process, clients must stop working and issue CQSDISC requests to disconnect from CQS. After all clients have disconnected, CQS terminates all tasks and returns control to z/OS.

Parameter Description:

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration token that uniquely identifies the client’s connection to CQS. The registration token is returned by the CQSREG request.

**ECB=ecbaddress**
Four-byte input parameter that specifies the address of the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise, it is processed synchronously.

**PARM=parmaddress**
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the value `CQSSHUT_PARM_LEN` (defined using the `FUNC=DSECT request`).

**RETCODE=returncodeaddress**
Output parameter that specifies the address of a 4-byte field to contain the CQSSHUT return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

**RSNCODE=reasoncodeaddress**
Four-byte output parameter that specifies the address of a field to contain the CQSSHUT reason code.

Return and reason codes for CQSSHUT

The following table lists the return and reason code combinations that can be returned for CQSSHUT requests. Use a CQSSHUT `FUNC=DSECT` request to include equate statements in your program for the return and reason codes.

</tbody>
</table>
CQSUNLCK request

A CQSUNLCK request unlocks one or more data objects and moves them into the first or last position on the queue. You can also force an unlock by specifying FUNC=FORCE.

Format for CQSUNLCK

DSECT function of CQSUNLCK

You use the DSECT function of a CQSUNLCK request to include equate (EQU) statements in your program for the CQSUNLCK parameter list length and CQSUNLCK return and reason codes.

UNLOCK function of CQSUNLCK

Use the UNLOCK function of a CQSUNLCK request to unlock one or more data objects and move them to the end or beginning of the queue.

FORCE function of CQSUNLCK

Use the FORCE function of a CQSUNLCK request to forcibly unlock data objects read from the specified queue type by the specified failed CQS client and clean up CQS’s knowledge of the data objects.

Usage of CQSUNLCK

Restriction: The CQSUNLCK request is not supported for resource structures.
A CQSUNLCK FUNC=UNLOCK request unlocks one or more data objects and moves them into the first or last position on the queue. The client passes an unlock list that contains one or more list entries, where each entry is a separate unlock request. A successful CQSUNLCK request invalidates the lock token and makes the data object available to any client for a CQSBRWSE, CQSDEL, CQSMOVE, or CQSREAD request.

The CQSUNLCK FUNC=FORCE request enables a CQS client to forcibly unlock data objects read from the specified queue type by the specified failed CQS client, so that the data objects do not remain on the LOCKQ until the failed CQS client restarts. Force unlock also removes the CQS’s knowledge of locked data objects, if this CQS processed the CQSREAD requests that locked the data objects.

When a CQS client fails, its locked data objects remain on the LOCKQ until the CQS client restarts, resyncs with CQS, and decides what to do with the locked data objects, or until a CQS client forcibly unlocks the data objects. Locked data objects are not accessible by other CQS clients.

Attention: CQS clients should use the CQSUNLCK FUNC=FORCE request with caution. The CQS clients in an IMSplex must apply the following force unlock rules consistently. If not used consistently, the CQSRSYNC request might fail, data objects might remain on the lock queue, read tables might remain in CQS, or data objects might be moved to the COLDQ. When using CQSUNLCK FUNC=FORCE, apply the following rules:

- Define IMSplex with CSL.
  The IMSplex must be defined with a Common Service Layer, so that CQS clients are notified when a CQS client fails.
- Select queue type candidates.
  Select one or more queue types whose data objects are candidates to be forcibly unlocked. All of the data objects with the specified queue type are candidates. There is no way to select specific data objects of a queue type to be forcibly unlocked.
- Forcibly unlock another CQS client’s data objects when CQS client fails.
  When a CQS client fails, it may leave locked data objects on the LOCKQ. Another CQS client should issue the CQSUNLCK FUNC=FORCE request, so that data objects do not remain on the LOCKQ until the failed CQS client restarts.
  Issue a CQSUNLCK FUNC=FORCE request only to forcibly unlock data objects of a CQS client that is currently not active. It is up to the CQS client issuing the CQSUNLCK FUNC=FORCE request to ensure that the target CQS client is not active.
  It is up to the CQS clients in the IMSplex to ensure that only one CQS client issues the CQSUNLCK FUNC=FORCE request. All members in an IMSplex defined with a CSL are notified when a member fails. Multiple CQSUNLCK FUNC=FORCE requests may have the following undesirable results:
  - Unnecessary CF accesses.
    The CQSUNLCK FUNC=FORCE request incurs multiple CF accesses to look at data objects on the candidate queue type. If multiple CQSUNLCK FUNC=FORCE requests are issued, each request makes the same numerous CF accesses. These extra CF accesses are unnecessary and incur additional performance overhead. If the performance overhead of unnecessary CF accesses is unacceptable, it is up to the CQS clients in the IMSplex to ensure that only one CQS client issues the CQSUNLCK FUNC=FORCE.
It is up to the CQS clients in the IMSplex to ensure that exactly one CQS client issues the CQSUNLCK FUNC=FORCE request successfully. If a CQS client issues the CQSUNLCK FUNC=FORCE request and a failure occurs, such as CQSUNLCK error, structure failure, loss of link, and so on, then the CQS clients in the IMSplex must ensure that the CQSUNLCK FUNC=FORCE request is issued successfully after the error is corrected.

- Data objects incorrectly unlocked.
  If a failed CQS client initializes right away, it might forcibly unlock its own data objects, resync with CQS, and put new data objects on the queue structure, before another CQS client attempts to forcibly unlock the failed CQS client's data objects. The other CQS client could incorrectly unlock data objects for UOWs that are in flight. It is up to the CQS clients in the IMSplex to ensure that exactly one CQS client forcibly unlocks data objects for the specified client.

- Forcibly unlock CQS client's own data objects when CQS client initializes.
  When a CQS client initializes, it should forcibly unlock its own data objects before issuing CQSRSYNC. This ensures that the CQS client's data objects are unlocked before resync, in case no other CQS client was available at failure time to do the force unlock. Force unlock also cleans up CQS's knowledge of the IMS client's locked data objects, since this CQS processed the CQSREAD request that locked the data objects.

- Resync with CQS, handling UOWs that are candidates for unlock force.
  When building the resync list to pass to CQS on the CQSRSYNC request, mark all candidates for the UNLOCK FORCE with a CQS client status of forced. CQS resync checks for the client status of forced and sets the UOWs to a CQS status of unlock in sync.

- Forcibly unlock other failed CQS clients' data objects when CQS client initializes.
  When a CQS client initializes, it should forcibly unlock the data objects of failed CQS clients, in case no other CQS client was available to do the force unlock when the CQS clients failed. After an initializing CQS client resyncs with CQS, it should issue one CQSUNLCK FUNC=FORCE request per failed CQS client, to forcibly unlock data objects on the candidate queue types.

**Parameter Description:**

**CLIENT=clientnameaddress**
Eight-byte input field that specifies the CQS client for which to forcibly unlock data objects. The client name is the same name specified on the CQSREG request when the client registered to CQS. A CQS client can forcibly unlock its own locked data objects before issuing the CQSRSYNC request. A CQS client can forcibly unlock another CQS client's locked data objects after issuing the CQSRSYNC request.

**CONTOKEN=connecttokenaddress**
Input parameter that specifies the address of the 16-byte connect token that uniquely identifies the client's connection to a particular coupling facility structure managed by this CQS. The connect token is returned by the CQSCONN request.

**COUNT=count**
Four-byte input parameter that specifies the number of list entries in the unlock list or four-byte output parameter to receive the count of data objects that were forcibly unlocked.

**CQSTOKEN=cqstokenaddress**
Input parameter that specifies the address of the 16-byte CQS registration
token that uniquely identifies the client’s connection to CQS. The registration
token is returned by the CQSREG request.

**ECB=ecbaddress**
Four-byte input parameter that specifies the address of the z/OS event control
block (ECB) used for asynchronous requests. If ECB is specified, the request is
processed asynchronously; otherwise it is processed synchronously.

**LIST=listaddress**
Four-byte input parameter that specifies the address of the unlock list. Each
entry is a separate CQSUNLCK request. Some fields in each entry must be
initialized by the client prior to the CQSUNLCK request. Other fields are
returned by CQS upon completion of the CQSUNLCK request.

The CQSUNLL list entry DSECT maps the list entries and can be used by the
client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following:

**compcodex**
Four-byte output field to receive the completion code from the request.
Possible completion codes are:

X'00000000'
Request completed successfully.

X'00000004'
locktoken is invalid.

X'00000008'
Structure inaccessible. Retry request later.

X'0000000C'
Unable to unlock the data object, because the original queue
for the data object is full. No data objects can be moved to the
named queue, but CQSUNLCK requests for other queues are
allowed.

X'00000010'
CQS internal error.

X'00000014'
Data object was lost because the structure was rebuilt. The data
object was nonrecoverable and a rebuild occurred after the
data object was locked. The data object is now lost.

**qpos**
One-byte input parameter that indicates the position on the queue to
which the unlocked element is to be added.

X'00'
Original client queue position. If the CQSREAD request that
locked this data object read the first data object, this request
unlocks the data object and adds it to beginning of the queue.
If the CQSREAD request read the last data object, this request
unlocks the data object and adds it to the end of the queue.

X'01'
End of queue.

X'02'
Beginning of queue.

**locktoken**
Sixteen-byte input parameter that specifies the lock token that uniquely
identifies the data object locked by a CQSREAD request. This
parameter is required.
LISTVER=1 | listversion
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSUNLCK request to include equate (EQU) statements in your program for the CQSUNLCK list versions.

PARM=paramaddress
Four-byte input parameter that specifies the address of a parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSUNLCK_PARM_LEN (defined using the FUNC=DSECT request).

QTYPE=queuetype
Four-byte input parameter that specifies the queue type from which the locked data objects were read. Valid values for the queue type are from 1 to 255 (decimal).

RETCODE=returncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSUNLCK request return code.

If the return code in register 15 is nonzero, the values in the return and reason code fields are invalid, because the CQS interface detected an error and was unable to send the request to CQS.

RSNCODE=reasoncodeaddress
Output parameter that specifies the address of a 4-byte field to contain the CQSUNLCK request reason code.

Return and reason codes for CQSUNLCK

The following table lists the return and reason code combinations that can be returned for CQSUNLCK requests. Use a CQSUNLCK FUNC=DSECT request to include equate statements in your program for the return and reason codes.

</table>
CQSUPD request

The CQSUPD request creates or updates one or more uniquely named resources on a resource structure. The CQSUPD request creates a resource if it does not exist, or updates a resource if it does exist.

Format for CQSUPD

DSECT function of CQSUPD

You use the DSECT function of a CQSUPD request to include equate (EQU) statements in your program for the CQSUPD parameter list length, the CQSUPD return and reason codes, the CQSUPD parmlist version, and the CQSUPD list version.

►►CQSUPD—FUNC=DSECT◄◄

UPDATE function of CQSUPD

Use the UPDATE function of a CQSUPD request to create or update one or more uniquely named resources on a resource structure. Each resource can optionally include a small client data area (DATA1) or a large client data area (DATA2).

►►CQSUPD—FUNC=UPDATE—CQSTOKEN=cqstokenaddress◄◄

►—CONTOKEN=connecttokenaddress—PARM=parmaddress—LIST=resourcelistaddress◄◄

►—LISTSIZE=listsize—LISTVER=1—COUNT=resourcelistcount◄◄

►—ECB=ecbaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress◄◄

Usage of CQSUPD

A CQSUPD creates or updates one or more uniquely named resources on a resource structure. CQSUPD creates a resource if it does not exist, or updates a resource if it does exist. A resource can be created or updated with or without client data. Examples of resources include transactions and control blocks.

Parameter Description:

CONTOKEN=connecttokenaddress
Address of a 16-byte input parameter that specifies the connect token that uniquely identifies the client’s connection to a particular coupling facility structure managed by CQS. The connect token is returned by the CQSCONN request.

COUNT=resourcelistcount
Four-byte input parameter that specifies the number of entries in the list.
CQSTOKEN=cqstokenaddress
Address of a 16-byte input parameter that specifies the CQS registration token that uniquely identifies the client's connection to CQS. The registration token is returned by the CQSREG request.

ECB=ecbaddress
Address of a 4-byte input parameter that specifies the z/OS event control block (ECB) used for asynchronous requests. If ECB is specified, the request is processed asynchronously; otherwise, it is processed synchronously.

LISTSIZE=resourcelistsize
Four-byte input parameter that specifies the size of the resource list. The list size must be specified because each entry in the list might have a variable length.

LISTVER=1 | listversion
Input parameter that specifies an equate for the list version. Use the DSECT function of a CQSUPD request to include equate (EQU) statements in your program for the CQSUPD list versions.

LIST=resourcelistaddress
Address of an input parameter that specifies a variable size resource list containing one or more entries. Each entry is a separate update request. Some fields in each entry must be initialized by the client prior to the CQSUPD request. Other fields are returned by CQS upon completion of the request.

The CQSUPDL list entry DSECT maps the list entries and can be used by the client. Multiple list entries must reside in contiguous storage.

Each list entry contains the following fields:

listentrylength
Four-byte input field that specifies the length of the list entry. The list entry length is variable, depending upon the data length, if specified. This parameter is required.

resourceid
Twelve-byte input field that contains the unique identifier of the resource to be created or updated on the resource structure. The resource identifier is unique in the IMSplex. The resource identifier consists of a 1-byte name type followed by an 11-byte client-defined resource name. The name type ensures uniqueness of client-defined names for resources with the same name type. Resources of different resource types can have the same name type. Valid values for the name type are decimal numbers from 1 to 255. The client-defined name has meaning to the client and consists of alphanumeric characters. This parameter is required.

resourcetype
One-byte field that specifies the resource type. The resource type is a client-defined physical grouping of resources on the resource structure. Valid values for the resource type are decimal numbers from 1 to 255. If the resource type is greater than the maximum number of resource types defined by CQS (11), it is folded into one of the existing resource types. This parameter is required.

reserved
Three-byte reserved field.
**options**

Four-byte input field that specifies update options. This parameter is optional. Possible options are:

- **X'80000000'**
  Return `data1` and `owner`, if update fails because of a version mismatch. This incurs the performance overhead of an additional CF access.

- **X'40000000'**
  Return `data2`, `data1`, and `owner` if update fails because of version mismatch. The `data2` is returned if `data2buffer` and `data2buffersize` are specified. This incurs the performance overhead of an additional CF access.

- **X'20000000'**
  Delete `data2`.

**compcode**

Four-byte output field to receive the completion code from the request. Possible completion codes are:

- **X'00000000'**
  Request completed successfully.

- **X'00000004'**
  Request succeeded successfully, but only partial data returned in `data2buffer`.

- **X'00000020'**
  `Resourceid` is invalid. The name type must be a decimal number from 1 to 255.

- **X'00000024'**
  CQS internal error.

- **X'00000028'**
  Version doesn't match that of existing resource.

- **X'00000030'**
  Resource already exists as a different name type.

- **X'00000034'**
  Structure is full.

- **X'00000038'**
  `ResourceType` is invalid. The resource type must be a decimal number from 1 to 255.

- **X'0000003C'**
  `Listentrylength` is invalid. The list entry length must be a non-zero number greater than or equal to the minimum list entry length. See the CQSUPDL DSECT.

- **X'00000040'**
  Structure is inaccessible.

- **X'00000044'**
  No CQS address space.

**version**

Eight-byte input and output field that specifies the version of a resource. The version is the number of times the resource has been updated. For the initial CQSUPD request to create the resource, `version`
must be zero on input. For a subsequent CQSUPD request to update an existing resource, version must match the existing resource's version. The CQSUPD request increments the version by 1, updates the resource with the new version, and returns the new version as output. If a CQSUPD request to update an existing resource fails because of a version mismatch, CQS returns the correct version to the client as output. This parameter is required. If the data object is created, version is ignored on input and a version of 1 is returned as output.

owner Eight-byte input and output field that specifies the owner of a resource. On input, owner is set for the resource. Specify zeroes to set no owner of a resource. Only one owner is permitted. If the update request fails because of a version mismatch and the option to return the owner is specified, the owner of the existing resource is returned as output. This parameter is required.

data1 Twenty-four-byte input and output field that specifies data1, a small piece of client data for the resource to be updated. Specify zeroes to set no client data in data1. If the CQSUPD request fails because of a version mismatch and the option to return data1 is specified, data1 of the existing resource is returned as output. The performance of accessing the client data specified by data1 is faster than accessing client data specified by data2. This parameter is required.

data2size Four-byte input and output field that specifies the size of client data data2 in data2buffer for the resource to be updated. Specify zero on input, if there is no data2 to update. If the CQSUPD request fails because of a version mismatch and the option to return data2 is set, the data2 size of the existing resource is returned as output. This parameter is optional.

data2buffersize Four-byte input field that specifies the size of the data2buffer containing the client data data2 for the resource to be updated or returned as output. The maximum size that can be specified is 61312 bytes (X'EF80'). Specify zero if data2 does not need to be updated or returned as output. This parameter is optional.

data2buffer Variable size input and output buffer that specifies data2, a large piece of client data for the resource to be updated. If the CQSUPD request fails because of a version mismatch and the option to return data2 is specified, data2 of the existing resource is returned, as much as fits into the data2buffer. This parameter is optional.

PARM=parmaddress
Address of an input parameter list used by the request to pass parameters to CQS. The length of the storage area must be at least equal to the EQU value CQSUPD_PARM_LEN (defined using the FUNC=DSECT request).

RETCODE=returncodeaddress
Address of a 4-byte output field to contain the CQSUPD return code. If the return code in register 15 is non-zero, the values returned for returncodeaddress and reasoncodeaddress are not valid because CQS detected an error and did not process the request.

RSNCODE=reasoncodeaddress
Address of a 4-byte output field to contain the CQSUPD reason code.
## Return and reason codes for CQSUPD

The following table lists the return and reason codes that can be returned for CQSUPD requests. Use a CQSUPD=DSECT request to include equate statements in your program for the return and reason codes.

</table>
Part 2. Common Service Layer (CSL)

The topics included in this information provide information about the CSL.
Chapter 3. Writing a CSL client

These topics describe the considerations for writing a CSL client. This information is for the programmer who writes the client, but also for the CSL administrator or IMS system programmer who must be aware of the issues involved in designing and writing a CSL client.

Event Control Blocks with CSL requests

The event control block (ECB) is an optional parameter within a CSL request that allows you to specify the address of the z/OS ECB.

Most CSL requests allow an ECB to be specified. The ECB parameter is optional and specifies the address of the z/OS ECB. When a CSL request completes, the ECB specified by the ECB parameter is posted. If the parameter is not included, the requesting module does not receive control until the request completes.

If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from the request before the invoker uses or examines any data that is returned by this request (including the RETCODE and RSNCODE fields). If the WAIT is not issued, the data might be invalid.

Environmental requirements for SCI requests

The environmental requirements for SCI requests depend on the SCI interface that is assigned to the client.

The following table describes the environment for authorized SCI requests.

<table>
<thead>
<tr>
<th>Environmental characteristic</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>Supervisor state (PSW key must match the PSW key when the CSLSCREG request was issued)</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>Any, however, PASN must equal the primary address space where the CSLSCREG request was issued</td>
</tr>
<tr>
<td>AMODE</td>
<td>31</td>
</tr>
<tr>
<td>ASC Mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Home address space</td>
<td>Any</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for interrupts</td>
</tr>
<tr>
<td>Control parameters</td>
<td>In primary address space</td>
</tr>
</tbody>
</table>

The following table describes the environment for non-authorized SCI requests.
Table 28. Environment for SCI requests using the non-authorized interface

<table>
<thead>
<tr>
<th>Environmental characteristic</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>Problem state (PSW key must match the PSW key when the CSLSCREG request was issued)</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>None (PASN=SASN=HASN)</td>
</tr>
<tr>
<td>AMODE</td>
<td>31</td>
</tr>
<tr>
<td>ASC Mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Home address space</td>
<td>Address space where CSLSCREG was issued</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for interrupts</td>
</tr>
<tr>
<td>Control parameters</td>
<td>In primary address space</td>
</tr>
</tbody>
</table>

The environmental requirements for the SCI register and deregister requests (CSLSCREG and CSLSCDRG) are different from all of the other SCI requests. Authorized clients must issue CSLSCREG and CSLSCDRG requests in the environment shown in the following table:

Table 29. Environment for CSLSCREG and CSLSCDRG requests using the authorized interface

<table>
<thead>
<tr>
<th>Environmental Characteristic</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Authorization</td>
<td>Supervisor state</td>
</tr>
<tr>
<td>Dispatchable unit mode</td>
<td>Task</td>
</tr>
<tr>
<td>Cross memory mode</td>
<td>None (PASN=SASN=HASN)</td>
</tr>
<tr>
<td>AMODE</td>
<td>31</td>
</tr>
<tr>
<td>ASC Mode</td>
<td>Primary</td>
</tr>
<tr>
<td>Locks</td>
<td>No locks held</td>
</tr>
<tr>
<td>Interrupt status</td>
<td>Enabled for interrupts</td>
</tr>
<tr>
<td>Control parameters</td>
<td>In primary address space</td>
</tr>
</tbody>
</table>

Non-authorized clients must issue CSLSCREG and CSLSCDRG requests in the environment described in the following table:

Table 30. Environment for CSLSCREG and CSLSCDRG requests using the non-authorized interface

<table>
<thead>
<tr>

</tbody>
</table>
How to interpret CSL request return and reason codes

Common Service Layer (CSL) return and reason codes indicate the success or failure of sending the request to the CSL address space and reflect the success or failure of the particular CSL request that is being made.

Each of the CSL requests receives a return and reason code that indicates the result of the specified request. Because most of the requests involve more than one component, return and reason codes can originate from any of the components involved. For example, a Structured Call Interface (SCI) return and reason code can be received because SCI is the communications mechanism for these requests. The high order byte is used to help identify the component that set the return and reason codes.

The possible values of the high-order byte and the meanings of each value are:

- X'00' IMS set the return and reason code
- X'01' SCI set the return and reason code
- X'02' Operations Manager (OM) set the return and reason code
- X'03' Resource Manager (RM) set the return and reason code
- X'04' ODBM set the return and reason code

Each of the CSL requests have a table of return and reason codes. If you are unable to find the return and reason code for the request that you issued, use the high order byte in the return code to help identify the component that set the return and reason code. For example, if the reason code is X'01' (SCI), you should start by looking at the return and reason codes for the CSLSCMSG and CSLSCRQS macros.

ODBM reason codes are defined in the CSLDRR macro, OM reason codes are defined in the CSLORR macro, RM reason codes are defined in the CSLRRR macro, and SCI reason codes are defined in the CSLSRR macro. These macros can be found in the IMS.SDFSMAC data set.

Planning considerations for writing clients for the CSL

Planning tasks are decisions that you must make to determine how you use the CSL managers and CSL requests.

Planning tasks are decisions that you must make to determine how you use the CSL managers. These decisions include:

- **What authorization level to use**
  You must decide whether your program needs to run authorized (supervisor state) or non-authorized (problem state). SCI initializes the appropriate environment based on your program's state and PSW key when it registers with SCI.

  **Note:** A non-authorized client cannot register with RM, issue RM requests, register commands with OM, or process requests issued using CSLSCRQS.

- **Whether to use SCI exit routines**
You must decide whether to use the SCI Input and Notify exit routines. An OM command processing client, for example, must have the SCI Input exit to process OM directives; it must have the SCI Notify exit to be notified when new OMs join the IMSplex, so the OM command processing client can register to those OMs.

- **TCB association**

  SCI registration (with the CSLSCREG request) enables an IMSplex member to be associated with a specific, different TCB. The authorization level you use must also be considered regarding TCB association. SCI internally associates the registration with the specified TCB. If no TCB is specified, SCI associates the registration with the TCB from which the registration is issued. If the associated TCB terminates without a deregistration being issued, SCI abnormally terminates the registration and releases the associated storage that SCI allocated in the member address space. If a subsequent SCI request is issued, an abend may occur.

- **Whether to use RM services, OM services, or ODBM services**

  You can choose to manage your own global resources. However, if you want to access IMS global resources, you must code an RM client.

  If you plan to develop your own command set and your own command processing client (which would coordinate its own command registration and security), you can write an OM command processing client. If you plan to develop your own SPOC or AOP to enter your own commands, you can write an OM AOP client. OM's role is to transport commands throughout an IMSplex and to consolidate those command responses, in XML tags, for a SPOC or AOP.

  For access to IMS databases managed by IMS DB in either the DBCTL or DB/DC environment, you can write an ODBM client application program that does not use IMS transactions. ODBM manages database connections in an IMSplex, permitting application programs that use either the IMS Universal drivers or the ODBA interface to access databases in an IMSplex. ODBM also protects the IMS control region from the unexpected termination of application programs that use the ODBA interface.

- **Whether to use message or request protocol when issuing requests**

  Use message protocol either when you do not need a synchronous response, or when you want an asynchronous response. IMSplex command responses that are sent with message protocol are sent asynchronously.

- **Whether to use the CSL OM audit trail**

  The CSL OM audit trail contains normal operating messages generated by active CSL address spaces including RM, OM, and SCI, as well as operational messages created by IMS components routing activity through a CSL component. CSL client activity is also captured. The audit trail can be used for audit compliance as well as for diagnostic tasks.

**Related concepts:**

- CSL OM audit trail (System Administration)

- BPE-based CSL SCI user exit routines (Exit Routines)

---

**Registration of CSL managers with SCI**

ODBM, OM, and RM clients must register with the Structured Call Interface (SCI). You must complete several registration steps in order to use any of the CSL managers.
To use any of the CSL managers, you must first complete registration steps. ODBM, OM, and RM clients must register with the SCI. This topic describes SCI registration and how ODBM, OM, and RM clients register with the SCI, how to set SCI to a ready state, and the sequence in which CSL requests must be issued.

**SCI registration**

You must register to SCI in order to uniquely identify an IMSplex member’s connection to SCI that is used on all subsequent requests.

When you register to SCI, you identify:

- The name of the IMSplex.
- Your client name, which must be unique if it is an authorized client.
- Exit routines, if you elect to use them.
- Your type of address space.
  
  Use a type of AOP or OTHER for the address space. Defining your address space by a type that is not AOP or OTHER could interfere with IMS address spaces. You can further identify your client by using the SUBTYPE parameter.

After you register to SCI, an SCI token is returned. The token uniquely identifies an IMSplex member’s connection to SCI and is used on all subsequent requests. Save the token for future ODBM, OM, RM, and SCI requests.

**Registering an ODBM client**

To register with ODBM, a client must first register with the CSL SCI and then with all active ODBMs in the IMSplex.

Application servers for application programs that use the IMS ODBA interface to access IMS databases can register with ODBM as a client. ODBM manages connections to databases owned by IMS DB systems in an IMSplex and protects IMS control regions from the unexpected termination of the application program.

To register an ODBM client:

1. Identify the exit routines that are needed to drive interactions between the CSL SCI and the client. The SCI handles communications between all CSL managers in the IMSplex and their client applications.

   a. Identify the SCI Notify exit for the client. A database connection can be routed through any active ODBM in the IMSplex, so an ODBM client must registered to all ODBMs. A SCI Notify exit is driven when a new ODBM becomes active in the IMSplex and notifies the client with information about the new ODBM. The client can then register to the new ODBM. The SCI Notify exit is identified with the NOTIFYEXIT parameter of the CSLSCREG request.

   b. Identify the SCI Input exit for the client with the INPUTEXIT parameter of the CSLSCREG request. An ODBM client must be able to receive ODBM directives sent from any ODBM in the IMSplex. The SCI Input exit is driven when there is a message or request for the client, so that the client can receive and process it.

2. Issue the CSLSCREG request to SCI with the information gathered in step 1. A client must register to the CSL SCI in the IMSplex before it can register with a CSL manager such as ODBM.

3. Issue the CSLSCQRY request to SCI to determine which instances of ODBM are active in the IMSplex. Before registering with the ODBMs for the first time, the
client must manually identify all active ODBMs with this request. Once registered, the SCI Notify exit automatically informs the client when new ODBMs become active.

4. Issue the CSLDMREG request to all ODBMs in the IMSplex that are reachable and ready to accept registration requests.

Consult the sequence of ODBM client requests for more information about managing the CSL registrations for an ODBM client.

Related concepts:
“Sequence of ODBM client requests” on page 143

Related reference:
“CSLSCREG: registration request” on page 240
“CSLDMREG: ODBM client registration request” on page 157

Registering an OM command processing client

An Operations Manager (OM) command processing client must register its command with OM, whereas automated operator program (AOP) clients do not have to register to OM.

Perform the following steps to register an OM command processing client in an IMSplex:

1. Identify the exit routines that are needed to drive interactions between the CSL SCI and the client. The SCI handles communications between all CSL managers in the IMSplex and their client applications.
   a. Identify the SCI Notify exit for the client. A database connection can be routed through any active OM in the IMSplex, so an OM command processing client must register to all OMs. A SCI Notify exit is driven when a new OM becomes active in the IMSplex and notifies the client with information about the new OM. The client can then register to the new OM. The SCI Notify exit is identified with the NOTIFYEXIT parameter of the CSLSCREG request.
   b. Identify the SCI Input exit for the client with the INPUTEXIT parameter of the CSLSCREG request. An OM command processing client must be able to receive OM directives sent from any OM in the IMSplex. The SCI Input exit is driven when there is a message or request for the client, so that the client can receive and process it.

2. Issue the CSLSCREG request to SCI with the information gathered in step 1. A client must register to the CSL SCI in the IMSplex before it can register with a CSL manager such as OM.

3. Issue the CSLSCQRY request to SCI to determine which instances of OM are active in the IMSplex. Before registering with the OMs for the first time, the client must manually identify all active OMs with this request. Once registered, the SCI Notify exit automatically informs the client when new OMs become active.

4. Issue the CSLOMBLD request to build the command list that will be passed to OM.

5. Issue the CSLOMREG request to all OMs in the IMSplex that are reachable and ready to accept registration requests.

6. Issue the CSLOMRDY request to indicate that the client is ready to begin processing commands from OM.
Consult the sequence of OM command processing client requests for more information about managing the CSL registrations for an OM command processing client.

“CSL OM command processing client requests” on page 161

Registering an RM client
Register RM clients to manage resources and access IMSplex-wide processes.

The following steps describe how to register an RM client first with the IMSplex Structured Call Interface (SCI), and then with the RMs active in the IMSplex.

1. Identify the exit routines that are needed to drive interactions between the CSL SCI and the client. The SCI handles communications between all CSL managers in the IMSplex and their client applications.
   a. Identify the SCI Notify exit for the client. A database connection can be routed through any active RM in the IMSplex, so an RM client must registered to all RMs. A SCI Notify exit is driven when a new RM becomes active in the IMSplex and notifies the client with information about the new RM. The client can then register to the new RM. The SCI Notify exit is identified with the NOTIFYEXIT parameter of the CSLSCREG request.
   b. Identify the SCI Input exit for the client with the INPUTEXIT parameter of the CSLSCREG request. An RM client must be able to receive RM directives sent from any RM in the IMSplex. The SCI Input exit is driven when there is a message or request for the client, so that the client can receive and process it.

2. Issue the CSLSCREG request to SCI with the information gathered in step 1. A client must register to the CSL SCI in the IMSplex before it can register with a CSL manager such as RM.

3. Issue the CSLSCQRY request to SCI to determine which instances of RM are active in the IMSplex. Before registering with the RMs for the first time, the client must manually identify all active RMs with this request. Once registered, the SCI Notify exit automatically informs the client when new RMs become active.

4. Issue the CSLRMREG request to all RMs in the IMSplex that are reachable and ready to accept registration requests. To manage global resources, register the resource type and associated name type.

How to enable SCI ready state
You use the CSLSCRDY request to enable an IMSplex member to receive messages and requests that are routed by type.

With the SCI, there are two states: registered and ready. The CSLSCRDY request enables an IMSplex member to receive messages and requests routed by type. An IMSplex member that is registered but has not issued a CSLSCRDY request can process only messages and requests that are specifically directed to it.

Sequence for coding CSL requests
Most Common Service Layer (CSL) requests must be issued in a certain sequence.

For more information about the sequence of issuing requests from various CSL clients, see the table in each of the following topics:
Requests common to all CSL components

Two requests, CSLZSHUT and CSLZQRY, are common requests that can be processed by all CSL components (OM, RM, and SCI).

CSLZQRY: query request

In an IMSplex, you might want to query statistics about one or more components in the CSL. You can write an IMSplex member program, for example, an automated operator program (AOP), that uses the CSLZQRY request to obtain statistics. Any member of an IMSplex can issue the CSLZQRY request.

CSLZQRY syntax

CSLZQRY DSECT syntax

Use FUNC=DSECT to include equate (EQU) statements in your program for the CSLZQRY parameter list length and the CSLZQRY return and reason codes.

CSLZQRY STATS syntax

Use FUNC=STATS to request statistics from ODBM, OM, RM, or SCI. The information that is returned from the CSLZQRY request is the same information that is passed to the STATS exit for that particular ODBM, OM, RM, or SCI.

CSLZQRY parameters

ECB=symbol

ECB=(r2-r12)

(Optional) - Specifies a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB
is specified, the invoker of the request must issue a WAIT (or equivalent) after
receiving control from CSLZQRY and before using or examining any data
returned by this request (including the RETCODE and RSNCODE fields).

MBRNAME=symbol
MBRNAME=(r2-r12)
(Required) - A 4-byte input parameter that specifies the address of the 8-byte
CSL member name to which to send the query.

OUTLEN=symbol
OUTLEN=(r2-r12)
(Required) - A 4-byte output parameter that is used to receive the length of the
output buffer. When the request returns, this word contains the length of the
buffer pointed to by the OUTPUT= parameter. The output length is zero if no
output is built, for example, when an error is detected before any output can
be built. When the caller is done with this storage, it is the caller's
responsibility to release the storage by issuing a CSLSCBFR request.

OUTPUT=outputbuffer
OUTPUT=(r2-r12)
(Required) - Specifies a 4-byte field to receive the address of the variable length
output returned by the CSLZQRY request. The output contains the results of
the CSLZQRY. The output length is returned in the OUTLEN= field. The
output address is zero if no output was built, for example, if an error was
detected before any output could be built. This buffer is not preallocated by
the caller. When the caller is done with this storage, it is the caller's
responsibility to release the storage by issuing a CSLSCBFR request.

PARM=symbol
PARM=(r2-r12)
(Required) - Specifies the CSLZQRY parameter list. The length of the
parameter list must be equal to the parameter list length EQU value defined by
ZQRY_PARMLN.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. This
can be returned by ODBM, OM, RM, or SCI. ODBM return codes are defined
in CSLDRR. OM return codes are defined in CSLORR. RM return codes are
defined in CSLRRR. SCI return codes are defined in CSLSRR.

RSNCODE=symbol
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. This
can be returned by ODBM, OM, RM, or SCI. ODBM reason codes are defined
in CSLDRR. OM reason codes are defined in CSLORR. RM reason codes are
defined in CSLRRR. SCI reason codes are defined in CSLSRR.

SCITOKEN=symbol
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token
uniquely identifies this connection to SCI. The SCI token was returned by a
successful CSLSCREG FUNC=REGISTER request.

CSLZQRY return and reason codes

The following table lists the return and reason codes that can be returned on a
CSLZQRY macro request. Also included is the meaning of a reason code (that is,
what possibly caused it).
## CSLZSHUT: shutdown request

CSLZSHUT is a programming interface that enables you to shut down one or more CSL components from an authorized IMSplex member. Because CSLZSHUT is sent as a message, control is returned to the program that issued the request after the message is sent.

CSLZSHUT allows you to terminate:
- A single CSL manager (ODBM, OM, RM, or SCI)
- A CSL and all of its components on a single z/OS image
- A CSL and all of its components for an IMSplex across multiple z/OS images

The CSLZSHUT request is sent as a message, so control returns to the program that issued the request after the request is sent.

To shut down a single CSL component, send the CSLZSHUT FUNC=QUIESCE,SCOPE=CSLMEMBER message to the component you want to shut down.

To shut down a CSL and all of its components on a single z/OS image, either:
- Send a CSLZSHUT FUNC=QUIESCE,SCOPE=CSLLOCAL message to the SCI that is active on the z/OS image that contains the CSL to be shut down.
- Send a CSLZSHUT FUNC=QUIESCE,SCOPE=CSLLOCAL,OSNAME=xxxx message to any SCI active in the IMSplex (where xxxx is the z/OS image where the CSL to be shut down is active). SCI sends a CSLZSHUT request to all of the CSL components to be shut down.

To shut down the CSL on an entire IMSplex, send a CSLZSHUT FUNC=QUIESCE,SCOPE=CSLPLEX message to any SCI active in the IMSplex. SCI sends a CSLZSHUT request to all the CSL components in the IMSplex.

### CSLZSHUT syntax

Use FUNC=DSECT to include equate (EQU) statements in your program for the CSLZSHUT parameter list length and the CSLZSHUT return and reason codes.

```
---CSLZSHUT---FUNC=DSECT---
```

### CSLZSHUT QUIESCE syntax

Use FUNC=QUIESCE to request that a CSL component shut down normally. Any work that the CSL component is currently processing is completed, and then the component shuts down. After processing the request, that component will not accept any new work.
If the component that is being shut down is an SCI, the IMSplex members that are currently registered with that SCI are not deregistered before SCI terminates. This can impact event notification. These IMSplex members cannot communicate with other IMSplex members because their SCI is shut down. If one or more of the “orphaned” members is shut down or fails, the other IMSplex members are not notified of the shutdown or failure event until SCI comes back online.

Notification of the shutdown or failure depends on the authorization level of the members. If the terminating member is non-authorized, other members are notified when SCI restarts. If the terminating member is authorized, other authorized members, including orphaned authorized members, are notified before SCI restarts.

**CSLZSHUT parameters**

- **MBRNAME**=**symbol**
  - (Required if SCOPE=CSLMEMBER) - Specifies the 8-byte CSL member name to which to send the shutdown request.

- **OSNAME**=**symbol**
  - (Optional if SCOPE=CSLLOCAL) - Specifies the 8-byte name of the CSL, running on the z/OS image, that is to be shut down. If the OSNAME parameter is specified and the SCI is not active on the z/OS image specified, the command will not be processed.

- **PARM**=**symbol**
  - (Required) - Specifies the CSLZSHUT parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by ZSHUT_PARMLEN.

- **RETCODE**=**symbol**
  - (Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

- **RSNCODE**=**symbol**
  - (Required) - Specifies a 4-byte field to receive the reason code on output. SCI reason codes are defined in CSLSRR. Possible return codes are described in the following table.

- **SCITOKEN**=**symbol**
  - (Required) - Specifies a 16-byte field containing the SCI token. This token
uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

**SCOPE=CSLMEMBER | CSLLOCAL | CSLPLEX**

(Required) - Specifies the scope of the CSL termination. Valid values for the SCOPE parameter are:

**CSLMEMBER**

This requests the CSL component receiving the request to shut itself down. CSLMEMBER can be processed by any CSL component.

**CSLLOCAL**

This requests that the CSL components on a single z/OS image be shut down. If the OSNAME parameter is also specified, the CSL components on that particular z/OS image are shut down. If the OSNAME parameter is specified and the SCI is not active on the z/OS image specified, the command will not be processed. If the OSNAME parameter is not specified, the SCI receiving the message shuts down the CSL on the local z/OS image. Only an SCI can process a SCOPE=CSLLOCAL request. If this request is sent to other CSL components, it is ignored.

**CSLPLEX**

This requests that the CSL components in an entire IMSplex be shut down. Only an SCI can process a SCOPE=CSLPLEX request. If this request is sent to other CSL components, it is ignored.

**CSLZSHUT return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLZSHUT macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'xx000008'</td>
<td>X'00002050'</td>
<td>The caller of the service attempted to pass an invalid parameter list. The request is rejected. &quot;xx&quot; identifies the component to set the return code.</td>
</tr>
</tbody>
</table>

"How to interpret CSL request return and reason codes" on page 105
Chapter 4. CSL automated operator program requests

Certain CSL requests can be used by AOP clients such as TSO SPOC in order to automate some of your operator programs. The following topics describe these requests in detail.

CSLOMCMD: command request

By using the CSLOMCMD request, your AOP client application that is running on the host can issue requests and send commands to OM.

Commands which are submitted through the OM API or REXX SPOC API use the address space identifier (ASID) USERID for authorization.

Commands which are submitted from a program using the OM API while executing in a TSO session use the TSO USERID for authorization.

Commands which are submitted from a program using the OM API while executing in a message processing program (MPP) region or batch message processing program (BMP) region use the IMS MPP/BMP dependent region USERID for authorization. In this environment, the actual transaction userid can be used for authorization if the user's installation uses the IMS Build Security Environment exit routine (DFSBSEX0) or OTMA/APPC SECURITY FULL (for example, the user's installation issues the /SECURE OTMA/APPC FULL command).

CSLOMCMD syntax

The syntax for CSLOMCMD can vary depending on what the automated operator client intends to perform.

**DSECT syntax**

Use the DSECT function of a CSLOMCMD request to include equate (EQU) statements in your program for the CSLOMCMD parameter list length and return and reason codes.

```plaintext
CSLOMCMD FUNC=DSECT
```

Request protocol syntax

For automation clients that want to wait for the output from the OM request, use this syntax.

```plaintext
CSLOMCMD FUNC=COMMAND ECB=ecb CMD=cmdinput CMDLEN=cmdinputlen
```
The response is passed back to the client after the request is completed.

Message protocol syntax

For automation clients that want to receive command output through their user exit, use this syntax.

The response is passed back to the client using the SCI Input exit. The client must have specified an SCI Input exit (INPUTEXIT=) on the SCI registration request (CSLSCREG) to receive a response.

CSLOMCMDC parameters

CMD=symbol

CMD=(r2–r12) (Required) - Specifies the command input buffer. This can be any IMS command that can be specified through the OM API. The first character of the command does not need to be a command recognition character (for example, /). The command recognition character does not control command routing in
OM. The ROUTE= keyword controls which IMSplex members receive a command. If a command recognition character is entered in the command string it is ignored. The first character in the command is considered a command recognition character if it is not a character between A-Z (either uppercase or lowercase).

**CMDLEN**=symbol
**CMDLEN**=(r2-r12)
(Required) - Specifies the length of the command input buffer.

**ECB**=symbol
**ECB**=(r2-r12)
(Optional) - Specifies the address of a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLOMCMD before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).

**OPTION**=aopoutput
**OPTION**=(r2-r12)
(Optional) - Use OPTION to return the format identifiers (FID) in the output from command processing clients. For example, when a type-1 /DISPLAY command is sent to an IMS command processing client, you can request that the FID be returned in each output line. The FID indicates to an AOI program how to map the line of output. The FID can be useful if you are converting existing AOI programs to OM AOI programs.

If OPTION is specified as a register, the register must contain the option value. For example, the value of AOPOUTPUT is 1. Therefore, the register must contain a 1.

The CSLOMCMD request contains the equate for the value of AOPOUTPUT. The DSECTS for the output of CSLOMCMD when OPTION=AOPOUTPUT are described in the DISPLAY macro in the IMS.SDFSMAC data set.

**OUTLEN**=symbol
**OUTLEN**=(r2-r12)
(Required for RQST) - Specifies a 4-byte field to receive the length of the output returned by the CSLOMCMD request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.

**OUTPUT**=output
**OUTPUT**=(r2-r12)
(Required for RQST) - Specifies a 4-byte field to receive the address of the variable length output returned by the CSLOMCMD request. The output contains the command response output. The output length is returned in the OUTLEN= field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the update output. It is the caller’s responsibility to release this storage by issuing the CSLSCBFR.
FUNC=RELEASE request when it is finished with the storage. The length of the output is returned in the OUTLEN= field.

**PARM=**symbol
**PARM=(r1-r12)**
(Required) - Specifies the CSLOMCMDC parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by OCMD_PARMN.

**PROTOCOL=RQST**
**PROTOCOL=MSG**
(Optional) - Specifies the SCI protocol for sending the request to OM.
- RQST - Send command to OM using the SCI request protocol.
- MSG - Send command to OM using the SCI message protocol.

**RETCODE=**symbol
**RETCODE=(r2-r12)**
(Required) - Specifies a 4-byte field to receive the return code on output. OM return codes are defined in the CSLORC. SCI return codes are defined in CSLSRR.

The return code can be from OM (CSLOMCMDC) or SCI (CSLSOMMSG or CSLSOMCQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. All return codes contain the SCI member type indicator for either SCI, OM, or RM in the high order byte (X'01' for SCI, X'02' for OM, X'03' for RM).

**RETNAME=**symbol
**RETNAME=(r2-r12)**
(Optional) - Specifies an 8-byte output field to receive the OM name. This is the CSL member name of the target address space to which SCI sent the request.

**RETTOKEN=**symbol
**RETTOKEN=(r2-r12)**
(Optional) - Specifies a 16-byte output field to receive the OM SCI token returned to the caller. This is the OM SCI token for the target address space to which the request was sent.

**ROUTE=**symbol
**ROUTE=(r2-r12)**
(Optional) - Specifies a route list that identifies OM clients (for example, IMS control regions) in the IMSplex to which the command is sent. If you do not specify ROUTE, OM routes to all clients that are registered and ready to process commands. If the route list specified consists of a SYSID of an OM client that is not registered for the specified command, then the command will fail with return and reason codes indicating the client is not registered for the command. For example, if a QUERY IMSPLEX command with ROUTE=IMS1 is processed by the OM address space and the IMS control region IMS1 is not registered for this command, then the command fails.
- To explicitly route the command to all command processing clients that have registered for and are ready to process commands, specify ROUTE=*.
- To route the command to the first command processing client which is READY and has MASTER capability, specify ROUTE=%. With ROUTE=%, OM routes the command to only one command processing client that OM chooses.

**Note:** Use commas to separate a list of client names.

**ROUTELEN=**symbol
ROUTELEN=(r2-r12)
(Optional) - Specifies the length of the list specified in the ROUTE= parameter.

RQSTTKN1=symbol
RQSTTKN1=(r2-r12)
(Optional) - Specifies a 16-byte user generated request token that is used to associate the request response with the request for asynchronous processing. RQSTTKN1 can include A-Z, 0-9, or printable characters (not case sensitive), except &, <, and >. OM returns the request token encapsulated in the <rqsttkn1/></rqsttkn1> tags in the XML output. OM converts any invalid data to periods (.) before returning XML output to the client. For PROTOCOL=MSG requests, OM also returns the address of this token in the OM Directive parameter list (mapped by CSLOMDIR macro) in the field ODIR_CQRT1PTR. This parameter must be 16 bytes and, if necessary, padded with blanks.

RSNCODE=symbol
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR.

SCITOKEN=symbol
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

TIMEOUT=timeoutvalue
TIMEOUT=symbol
TIMEOUT=(r2-r12)
(Optional) - Specifies a 4-byte command timeout value in seconds. If the TIMEOUT value is reached during OM command processing and before all clients have responded to the command, OM terminates the command and returns all available responses. If too small a value is specified, an incomplete response is returned. The TIMEOUT value ensures a response is returned even if a client processing the command is unable to respond. The TIMEOUT keyword is ignored if no CMD keyword is specified. If a command is requested but no timeout value is specified, a timeout value of 5 minutes is used.

If TIMEOUT is specified as a symbol, the symbol must be an EQU symbol equated to the timeout value. If TIMEOUT is specified as a number, the number must be the timeout value.

USERID=symbol
USERID=(r2-r12)
(Optional) - Specifies the 8-byte user ID to be used by RACF® or an equivalent security product. Use this parameter only if your client address space has been authorized for this request. If your client is unauthorized, the user ID is obtained automatically from z/OS control blocks. This user ID is intended for use by authorized system management address spaces that can issue an OM request on behalf of another address space or remote client. In this case, the user ID of the client address space is not the user ID of the actual client, so it must be passed to OM. This parameter must be 8 bytes, left-aligned, and, if necessary, padded with blanks.
Table 33. CSLOMCMD return and reason codes.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'02000004'</td>
<td>Any code</td>
<td>This return code indicates a warning. All or part of the request might have completed successfully. Additional information is returned with the response to the request.</td>
</tr>
<tr>
<td>X'00001000'</td>
<td></td>
<td>The command timed out before all of the command response information could be collected. One or more clients might not be responding or a client might have needed more time to process the command. If you specified the TIMEOUT option, make sure that the interval is long enough to allow the command to process. All command response information that is collected prior to the timeout is returned. This reason code is also returned if CSL members such as SCI or RM are not active on the local or remote z/OS image and cannot process the request or return a response. To obtain more information, issue QUERY IMSPLEX to determine which CSL members are inactive. Restart those members and re-issue the request. If this reason code is returned after an INIT OLC or TERM OLC command, issue QUERY MEMBER to determine the online change status of the IMS systems participating in the online change and take action based on their status.</td>
</tr>
<tr>
<td>X'00001004'</td>
<td></td>
<td>The INPUT exit rejected the command specified in the CMD field. The command was not processed.</td>
</tr>
<tr>
<td>X'00001008'</td>
<td></td>
<td>The client (specified in the corresponding XML &lt;mbr&gt;&lt;/mbr&gt; tags in the &lt;cmderr&gt; section) was specified in the ROUTE list for the command specified in the CMD field. The command was not routed to the command processing client because the client is not the master.</td>
</tr>
<tr>
<td>x'00001014'</td>
<td></td>
<td>Command completed with warnings. Check return codes. At least one client member returned return code 4 to the Operations Manager. All other clients returned a return code not greater than 4. Refer to the completion codes returned on the request for further information. If the command was successfully processed by one command processing client as designed, but all other command processing clients to which the command was routed either explicitly (in other words, the user specified a route list) or implicitly (in other words, the user did not specify a route list so the command was routed to ALL) received reason code x'00001000' (IRSN_NOTMSTR) for return code x'00000004', then the overall OM return/reason codes will be WARNING (02000004) / WARNING (00001014)</td>

CSLOMI: API request

With the CSLOMI request, your AOP client can communicate with a z/OS address space that acts as an OM AOP client. You can then issue OM requests and send QUERY commands to OM.

With the CSLOMI request, a z/OS automated operator client can issue an IMS command to or request OM-specific information from an OM. The CSLOMI macro interface is designed for use by system management address spaces that receive input from a workstation or other z/OS address space and must pass the request to OM. In this case the workstation application builds the input string and passes it to the z/OS address space. The z/OS address space passes the input string to OM on the INPUT= parameter.

Commands which are submitted through the OM API or REXX SPOC API use the address space identifier (ASID) USERID for authorization.

Commands which are submitted from a program using the OM API while executing in a TSO session use the TSO USERID for authorization.

Commands which are submitted from a program using the OM API while executing in a message processing program (MPP) region or batch message processing program (BMP) region use the IMS MPP/BMP dependent region USERID for authorization. In this environment, the actual transaction userid can be used for authorization if the user's installation uses the IMS Build Security Environment exit routine (DFSBSEX0) or OTMA/APPC SECURITY FULL (for example, the user's installation issues the /SECURE OTMA/APPC FULL command).

CSLOMI syntax

The syntax for CSLOMI can vary, depending on how the automated operator client wants to receive the command response. If the client does not have an input exit and wants to receive the command output as a response, use the request syntax. If the client does have an input exit and wants to receive the command output as a message, use the message syntax.

CSLOMI request protocol syntax

For automated clients that want to wait for output from the OM request, use this syntax.

```
CSLOMI—FUNC=OMAPI—ECB=ecb—INPUT=input—INLEN=inputlen

CSLOMI—OUTPUT=output—OUTLEN=outputlen—USERID=userid

CSLOMI—RQSTTKN1=requesttoken1—PARM=parm—PROTOCOL=RQST—RETCODE=returncode
```
After control is returned to the client (if ECB is not specified), or the ECB is posted (if an ECB is specified), the response is available to the client.

**CSLOMI message protocol syntax**

For automated clients that want to receive command output through their user exit, use this syntax:

```
CSLOMI FUNC=OMAPI INPUT=input INLEN=input USERID=userid
```

```
RQSTTKN1=requesttoken1 PARM=parm PROTOCOL=MSG RETCODE=returncode
```

```
RSNCODE=reasoncode RETNAME=returnname RETTOKEN=returntoken
```

```
SCITOKEN=scitoken
```

The response is passed back to the client using the SCI Input exit. The client must have specified an SCI Input exit (INPUTEXIT=) on the SCI registration request (CSLSCREG) to receive a response.

**CSLOMI Input= parameter syntax**

For other applications or workstations that do not communicate directly with OM, use this syntax.

```
A B C
```

```
RQSTTKN2(requesttoken2)
```

**A:**

```
CMD(command) OPTION(AOPOUTPUT) ROUTE (+)(client) (client)
```

```
TIMEOUT (timeoutvalue)
```

126 System Programming APIs
This syntax is used for the INPUT= parameter. The application builds the command or query, and passes it to a z/OS address space that communicates with OM directly.

**CSLOMI request and message parameters**

**ECB=-symbol**

*ECB=(r2-r12)*  
(Optional) - Specifies the address of a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLOMI before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).

**INLEN=-symbol**

*INLEN=(r2-r12)*  
(Required) - Specifies the length of the input buffer.

**INPUT=-symbol**

*INPUT=(r2-r12)*  
(Required) - Specifies the address of the input buffer. The following shows an example of the input buffer that is passed to CSLOMI. The input buffer is the character field MYINPUT and specifies three parameters: a command string of QRY TRAN SHOW(ALL), a timeout value of 360 seconds, and a route list consisting of one element, IMSA:

```
CSLOMI FUNC=OMAPI,INPUT=MYINPUT,INLEN=INLEN
INUTLEN DC A(MYINPUTL)
MYINPUT DC C'CMD (QRY TRAN SHOW(ALL) TIMEOUT(360) ROUTE(IMSA))'
MYINPUTL EQU *=MYINPUT
```

**OUTLEN=-symbol**

*OUTLEN=(r2-r12)*  
(Required for RQST) - Specifies a 4-byte field to receive the length of the output returned by the CSLOMI request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.

**OUTPUT=-symbol**

*OUTPUT=(r2-r12)*  
(Required) - Specifies a field to receive the variable length output returned by the CSLOMI request. The output contains the command response output. The output length is returned in the OUTLEN= field.
The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the update output. It is the caller's responsibility to release this storage by issuing the CSLSCBFBR FUNC=RELEASE request when it is finished with the storage. The length of the output is returned in the OUTLEN= field.

**PARM=** symbol
**PARM=(r2-r12)**
(Required) - Specifies the CSLOMI parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by OL_PARMLEN.

**PROTOCOL=RQST**
**PROTOCOL=MSG**
(Optional) - Specifies the SCI protocol for sending the request to OM.
- RQST - Send command to OM using the SCI request protocol.
- MSG - Send command to OM using the SCI message protocol.

**RETCODE=** symbol
**RETCODE=(r2-r12)**
(Required) - Specifies a 4-byte field to receive the return code on output. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

The return code can be from OM (CSLOMI) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. All return codes contain the SCI member type indicator for either SCI, OM, or RM in the high order byte (X'01' for SCI, X'02' for OM, X'03' for RM).

**RETNNAME=** symbol
**RETNNAME=(r2-r12)**
(Optional) - Specifies an 8-byte output field to receive the OM name. This is the CSL member name of the target address space to which SCI sent the request.

**RETTOKEN=** symbol
**RETTOKEN=(r2-r12)**
(Optional) - Specifies a 16-byte output field to receive the OM SCI token returned to the caller. This is the OM SCI token for the target address space to which the request was sent.

**RQSTTKN1=** symbol
**RQSTTKN1=(r2-r12)**
(Optional) - Specifies a 16-byte user generated request token that is used to associate the request response with the request for asynchronous processing. RQSTTKN1 can include A-Z, 0-9, or printable characters (not case sensitive), except & <, and >. OM returns the request token encapsulated in the <rqsttkn1></rqsttkn1> tags in the XML output. OM converts any invalid data to periods (.) before returning XML output to the client. For PROTOCOL=MSG requests, OM also returns the address of this token in the OM Directive parameter list (mapped by CSLOMDIR macro) in the field ODIR_CQRT1PTR. This parameter must be 16 bytes and, if necessary, padded with blanks.

**RSNRCODE=** symbol
**RSNRCODE=(r2-r12)**
(Required) - Specifies a 4-byte field to receive the reason code on output. OM
reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=-symbol**

**(Required)** - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

**USERID=-symbol**

**(Optional)** - Specifies the 8-byte user ID that should be used for security checking for the command and keyword combination. This user ID is used only if the client address space is an authorized caller. If the client address space is unauthorized, the user ID is obtained from z/OS control blocks. This user ID is intended for use by authorized system management address spaces that can issue an OM request on behalf of another address space or remote client. In this case, the user ID of the client address space is not the user ID of the actual client, so it must be passed to OM. This parameter must be 8 bytes, left-justified, and, if necessary, padded with blanks.

### CSLOMI Input= parameters

The parameters for the CSLOMI input option are for applications and workstations that do not communicate directly with OM.

**CMD(command)**

**(Required if QUERY is not specified)** - Specifies the command input buffer. This can be any IMS command that can be specified through the OM API. The first character of the command does not need to be a command recognition character (for example, `/`). The command recognition character does not control command routing in OM. The ROUTE keyword is used to control which IMSplex members receive a command. If a command recognition character is entered in the command string, it is ignored. The first character in the command is considered a command recognition character if it is not a character between A-Z (either uppercase or lowercase).

**CMDLANG(cmdlang)**

The language to be used for IMS command text that is returned on the request. This value defaults to the default established for the OM system specified on the OM startup parameter CMDLANG=. Currently the only accepted value is ENU for US English. If an invalid language is specified text in the OM default language is returned.

**OPTION(AOPOUTPUT)**

**(Optional, valid only for CMD())** - Specify the AOPOUTPUT option to return the format identifiers (FID) in the output from command processing clients. For example, when a type-1 /DISPLAY command is sent to an IMS command processing client, you can request that the FID be returned in each output line. The FID indicates to an AOI program how to map the line of output. The FID can be useful if you are converting existing AOI programs to OM AOI programs.

**QUERY(querytype)**

Type of query to be performed by OM.

**CMDCLIENTS**

Requests that OM return a list of all clients (for example, IMS control regions) that have registered to OM for command processing.
The list of clients is returned encapsulated in `<cmdclients> </cmdclients>` tags. `querytype` can be one of the following.

- `<mbr name=membername>`
  The member name is the name of the client address space.
  - `<typ> </typ>`
    The member type is the type of the client address space.
  - `<styp> </styp>`
    The member subtype is the subtype of the client address space.
  - `<vsn> </vsn>`
    The member version is the version of the client address space.
  - `<jobname> </jobname>`
    The client jobname is the jobname or the started task for the client address space.
- `</mbr>`

**CMDSYNTAX**
Requests that OM return a list of the XML representing the command syntax for selected commands registered with OM. Additionally, the translatable text associated with the command syntax is returned.

The command syntax XML is returned encapsulated in `<cmdsyntax> </cmdsyntax>` tags. The command syntax DTD is returned encapsulated in `<cmddtd> </cmddtd>` tags. The command syntax translatable text is returned encapsulated in `<cmdtext> </cmdtext>` tags.

**ROUTE(routeclist)**
(Optional) - Specifies a route list that identifies OM clients (for example, IMS control regions) in the IMSplex to which the command is sent. In the list, the clients are separated by commas. If you do not specify ROUTE, OM routes to all clients that are registered and ready to process commands.

- To explicitly route the command to all command processing clients that have registered for and are ready to process commands, specify ROUTE(*).
- To route the command to the first command processing client which is READY and has MASTER capability, specify ROUTE(%). With ROUTE(%), OM routes the command to only one command processing client that OM chooses.

**RQSTTKN2(requesttoken2)**
(Optional) - Specifies a 16-byte user generated request token that is used to associate the request response with the request for asynchronous processing. RQSTTKN2 can include A-Z, 0-9, or printable characters (not case sensitive), except &, <, and >. OM returns the request token encapsulated in the `<rqsttkn2> </rqsttkn2>` tags in the XML output. OM converts any invalid data to periods (.) before returning XML output to the originating client. For PROTOCOL=MSG requests, OM also returns the address of this token in the OM Directive parameter list (mapped by CSLOMDIR macro) in the field ODIR_CQRT2PTR.

**TIMEOUT(timeoutvalue )**
(Optional) - Specifies a 4-byte command timeout value in seconds. If the TIMEOUT value is reached during OM command processing before all clients have responded to the command, OM terminates the command and returns all available responses. If too small a value is specified, an incomplete response is returned. The TIMEOUT value ensures a response is returned even if a client processing the command cannot respond. The TIMEOUT keyword is ignored if
no CMD keyword is specified. If a command is requested but no timeout value is specified, a timeout value of 5 minutes is used.

**CSLOMI return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLOMI macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

*Table 34. CSLOMI return and reason codes*

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'02000004'</td>
<td>Any code</td>
<td>This return code represents a warning. All or part of the request might have completed successfully. Additional information is returned with the response to the request.</td>
</tr>
<tr>
<td>X'00001000'</td>
<td></td>
<td>The specified command timed out before all of the command response information could be collected. One or more clients might not be responding, or a client might have needed more time to process the command. If a TIMEOUT value is specified, ensure the value is long enough to allow for the command to be processed. All command response information that is collected prior to the timeout is returned.</td>
</tr>
<tr>
<td>X'00001004'</td>
<td></td>
<td>The INPUT exit rejected the command contained in the CMD field. The command was not processed.</td>
</tr>
<tr>
<td>X'00001008'</td>
<td></td>
<td>The client (specified in the corresponding XML &lt;mbr&gt;&lt;/mbr&gt; tags in the &lt;cmderr&gt; section) was specified in the ROUTE list for the command specified in the CMD field. The command was not routed to the command processing client because the client is not the master.</td>
</tr>
<tr>
<td>X'00001010'</td>
<td></td>
<td>The text file could not be loaded in the language specified on the CMDLANG parameter. The default language is used.</td>
</tr>
<tr>
<td>X'00001014'</td>
<td></td>
<td>The command completed with warnings. Check the return codes. At least one client member returned a return code 4 to the Operations Manager. All other clients returned a return code not greater than 4. If the command was successfully processed by one command processing client as designed, but all other command processing clients to which the command was routed received reason code X'00001000' (IRSN_NOTMSTR) for return code X'00000004', then the overall OM return and reason codes will be:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WARNING (X'02000004')</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• WARNING (X'00001014')</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Refer to the completion codes returned on the request for further information.</td>

### CSLOMQRY: query request

With the CSLOMQRY request, any AOP client that is running on the host can request OM-specific information.
CSLOMQRY syntax

The syntax for CSLOMQRY can vary depending on what the automated operator client intends to perform. Parameter descriptions for each syntax example are provided in the following section.

DSECT syntax

Use the DSECT function of a CSLOMQRY request to include equate (EQU) statements in your program for the CSLOMQRY parameter list length and return and reason codes.

```plaintext
►► CSLOMQRY—FUNC=DSECT
```

Request protocol syntax

For automation clients that want to wait for the output from the OM request, use this syntax.

```plaintext
►► CSLOMQRY—FUNC=QUERY—OUTPUT=output—OUTLEN=outputlen
        ECB=ecb

►► RQSTTKN1=requesttoken1
        TYPE=CMDCLIENTS
        CMDSYNTAX=cmdlang
        PROTOCOL=RQST
        RETCODE=returncode
        RSNCODE=reasoncode
        RETNAME=returnname
        RETTOKEN=returntoken
        SCITOKEN=scitoken
```

The response is passed back to the client after the request is completed.

Message protocol syntax

For automation clients that want to send a message to OM to process an OM request, use this syntax.

```plaintext
►► CSLOMQRY—FUNC=QUERY—RQSTTKN1=requesttoken1

►► TYPE=CMDCLIENTS
        CMDSYNTAX=cmdlang
        PROTOCOL=MSG
        PARM=parm
        RQST
        RETCODE=returncode
        RSNCODE=reasoncode
        RETNAME=returnname
        RETTOKEN=returntoken
        SCITOKEN=scitoken
```

Chapter 4. CSL automated operator program requests 135
The response is passed back to the client using the SCI Input exit. The client must have specified an SCI Input exit (INPUTEXIT=) on the SCI registration request (CSLSCREG) to receive a response.

**CSLOMQRY parameters**

**CMDLANG=cmdlang**
(Optional) - The language to be used for IMS command text that is returned on the request. This value defaults to the default established for the OM system specified on the OM startup parameter CMDLANG=. Currently the only accepted value is ENU for US English. If an invalid language is specified in OM, the default language is returned.

**ECB=symbol**
**ECB=(r2-r12)**
(Optional) - Specifies the address of a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLOMQRY before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).

**OUTLEN=symbol**
**OUTLEN=(r2-r12)**
(Required for RQST) - Specifies a 4-byte field to receive the length of the output returned by the CSLOMQRY request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.

**OUTPUT=**
**OUTPUT=(r2-r12)**
(Required) - Specifies a field to receive the variable length output returned by the CSLOMQRY request. The output contains the command response output. The output length is returned in the OUTLEN= field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the update output. It is the caller's responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is finished with the storage. The length of the output is returned in the OUTLEN= field.

**PARM=symbol**
**PARM=(r2-r12)**
(Required) - Four-byte input parameter that specifies the address of the storage used by the request to pass the parameters to SCI. The length of the parameter list must be equal to the parameter list length EQU value defined by OQRY_PARMLEN.

**PROTOCOL=RQST**
**PROTOCOL=MSG**
(Optional) - Specifies the SCI protocol for sending the request to OM.
- RQST - Send command to OM using the SCI request protocol.
- MSG - Send command to OM using the SCI message protocol.

**RETCODE=symbol**
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. OM return codes are defined in CSLORR. SCI return codes are defined in CSLSRR.

The return code can be from OM (CSLOMQRY) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. All return codes contain the SCI member type indicator for either SCI, OM, or RM in the high order byte (X'01' for SCI, X'02' for OM, X'03' for RM).

RETNAMEm
RETNAMEm=(r2-r12)
(Optional) - Specifies an 8-byte output field to receive the OM name. This is the CSL member name of the target address space to which SCI sent the request.

RETTOKEN=m
RETTOKEN=(r2-r12)
(Optional) - Specifies a 16-byte output field to receive the OM SCI token returned to the caller. This is the OM SCI token for the target address space to which the request was sent.

RQSTTKN1=m
RQSTTKN1=(r2-r12)
(Optional) - Specifies a 16-byte user generated request token that is used to associate the request response with the request for asynchronous processing. RQSTTKN1 can include A-Z, 0-9, or printable characters (not case sensitive), except &<>&. OM returns the request token encapsulated in the <rqtstk1/></rqtstk1> tags in the XML output. OM converts any invalid data to periods (.) before returning XML output to the client. For PROTOCOL=MSG requests, OM also returns the address of this token in the OM directive parameter list (mapped by CSLOMDIR macro) in the field ODIR_CQRT1PTR. This parameter must be 16 bytes and, if necessary, padded with blanks.

RSNCODE=m
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

SCITOKEN=m
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

TYPE=CMDCLIENTS
TYPE=CMDSYNTAX
(Required) - Four-byte input parameter that specifies the type of query to be performed by OM.

CMDCLIENTS
Requests that OM return a list of all clients (for example, IMS control regions) that have registered to OM for command processing.

The clients are returned encapsulated in <cmdclients> </cmdclients> tags.
- <mbr name=membername>
  The member name is the name of the client address space.
- <typ> </typ>
The member type is the type of the client address space.

- `<styp>` </styp>
The member subtype is the subtype of the client address space.

- `<vsn>` </vsn>
The version is the version of the client address space.

- `<jobname>` </jobname>
The client jobname is the jobname or the started task for the client address space.

- </mbr>

**CMDSYNTAX**
Requests that OM return a list of the XML representing the command syntax for selected commands registered with OM. Additionally, the translatable text associated with the command syntax is returned.

The command syntax XML is returned encapsulated in `<cmdsyntax>` </cmdsyntax> tags. The command syntax DTD is returned encapsulated in `<cmd.dtd>` </cmd.dtd> tags. The command syntax translatable text is returned encapsulated in `<cmdtext>` </cmdtext> tags.

The command syntax and translatable text that is returned as a result of the CSLOMQRY QUERY TYPE(CMDSYNTAX) request includes information for type-2 commands.

**CSLOMQRY return and reason codes**

The following table lists the return and reason code combinations that can be returned on a CSLOMQRY request and that are unique to the CSLOMQRY request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>

CSL OM automated operator program clients

OM provides an API interface for application programs that automate operator actions known as automated operator programs (AOP). You can use an AOP to issue commands that are embedded in an OM API request to an OM.

OM provides an application programming interface (API) for application programs that automate operator actions. These programs are called automated operator programs (AOP). An AOP issues commands that are embedded in an OM API request to an OM. The responses to those commands are returned to the AOP embedded in XML tags.

If you want to use OM to manage commands and command responses in an IMSplex for your own product or service, you can use an AOP client, such as each of these clients:

- The IMS-supplied AOP client, TSO single point of control (SPOC), which runs on the host. With the TSO SPOC, an automated operator can issue commands to the IMSplex and receive responses to those commands interactively.
- An AOP client that runs on a workstation (called a workstation SPOC).
- A command processing client, such as IMS.

An OM client uses OM requests to communicate with OM. Each OM client must register to SCI before it can issue OM requests.

If you intend to write AOPs, you can write them in either assembler or REXX. Assembler applications issue requests to the OM API; REXX applications issue REXX host commands to communicate with OM.

IMS provides a REXX SPOC API, which is a REXX program interface to a SPOC application. Your existing REXX applications can use this REXX SPOC API to interact with OM.

Chapter 9, “CSL Operations Manager XML output,” on page 257
How AOP clients that run on the host communicate with the CSL OM

Automated operator program (AOP) clients that run on the host can communicate directly with Operations Manager (OM). After a z/OS AOP is registered with SCI, it can issue an OM command (CSLOMCMC) or query (CSLOMQR) requests. When the z/OS AOP is ready to terminate, it must deregister with SCI using the CSLSCDFR macro. Each of the requests can be sent directly to OM or SCI.

The following table lists the sequence of requests that are issued from an AOP that is running on the host. The request is listed with its purpose.

**Table 36. Sequence of requests for an AOP OM client running on the host**

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSLSCREG</td>
<td>Registers to SCI, which enables the client to send OM requests to OM</td>
</tr>
<tr>
<td></td>
<td>through SCI.</td>
</tr>
<tr>
<td>CSLSCRDY</td>
<td>Readies the OM client to SCI, which routes messages to the client by</td>
</tr>
<tr>
<td></td>
<td>client type.</td>
</tr>
<tr>
<td>CSLOMxxx</td>
<td>Issues OM requests (CSLOMCMC, CSLOMQR) to send commands to OM.</td>
</tr>
<tr>
<td>CSLSCBFR</td>
<td>Releases the output buffer returned by the request, if any.</td>
</tr>
<tr>
<td>CSLSCQSC</td>
<td>Quiesces with SCI.</td>
</tr>
<tr>
<td>CSLSCDFR</td>
<td>Deregisters from SCI.</td>
</tr>
</tbody>
</table>

**Note:** Although not required for an AOP executing on the host, CSLSCRDY and CSLSCQSC are recommended for clients that want to receive messages routed by TYPE.

An OM client uses OM requests to access and use OM services and resources. Some SCI and OM requests must be issued by the client to request OM services. Some of those requests must be issued in a particular sequence, as shown in [Table 36](#). Other requests can be issued multiple times, in any order, based on the processing requirements of the client.

How AOP clients that run on a workstation communicate with the CSL OM

A workstation automated operator program (AOP) client cannot communicate directly with Operations Manager (OM). Instead, it must communicate with a z/OS address space that acts as an OM AOP client.

Instead of issuing CSLOMCMC or CSLOMQR requests, the z/OS address space issues CSLOMI, which passes the prebuilt string that it received from the workstation to OM. For example, if the workstation wants to query the command processing clients to see how many exist in the IMSplex, it can send the string QUERY(CMDCLIENTS) to the z/OS address space, which would then use CSLOMI to send the query to OM for command processing.

If the workstation wants to issue a QRY TRAN command to the IMSplex, it can send the following string to the z/OS address space:

```
CMD(QUERY TRAN NAME) ROUTE(IMSA) TIMEOUT(10) RQSTTKN2(QTRANCMD)
```
The z/OS address space would then use CSLOMI to send the string to OM for command processing. The z/OS address space should pass the user ID associated with the workstation application to ensure correct authorization processing by OM.

The following table illustrates the sequence of requests issued by a proxy AOP client, executing on z/OS, that is communicating with OM on behalf of a workstation AOP. The request is listed with its purpose.

Table 37. Sequence of requests for AOP running on the workstation

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSLSCREG</td>
<td>Registers to SCI, which enables the client to send OM requests to OM through SCI.</td>
</tr>
<tr>
<td>CSLSCRDY</td>
<td>Readies the OM client to SCI, which routes messages to the client by client type.</td>
</tr>
<tr>
<td>CSLOMI</td>
<td>Issues OM requests (CMD(), QUERY()) to send commands to OM.</td>
</tr>
<tr>
<td>CSLSCBFR</td>
<td>Releases the output buffer returned by the request, if any.</td>
</tr>
<tr>
<td>CSLSCQSC</td>
<td>Quiesces with SCI.</td>
</tr>
<tr>
<td>CSLSCDRG</td>
<td>Deregisters from SCI.</td>
</tr>
</tbody>
</table>

**Note:** Although not required for an AOP executing on the workstation, CSLSCRDY and CSLSCQSC are recommended for clients that want to receive messages routed by TYPE.

**Processing AOP commands with a command processing client**

A command processing client, such as an IMS control region, is a system that provides a command processor to accept and process commands entered by an automated operator program (AOP).

A command processing client must register to OM in addition to registering with SCI. The command processing client registers with OM by passing a list of commands to OM that it can process.

After successful command registration, the client must inform OM that it is ready to process commands.

Because AOP commands can be routed through any active OM in an IMSplex, a command processing client must register its command list and ready status with all active OMs. Registering with all OMs in the IMSplex ensures that any AOP command intended for the command processing client will be routed correctly, regardless of the OM that routes that command.

Like the AOP clients, command processing clients must issue requests in a particular sequence. This sequence, and the purpose of the request, is listed in Table 38.

Table 38. Sequence of requests for a command processing client

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>

</tr>
</tbody>
</table>

**Interpreting CSL OM XML output**

Command responses that are returned through the OM API are embedded in XML tags. XML output is generated for responses to the CSLOMI, CSLOMCMD, and CSLOMQRY requests. The DSECTS for the output of CSLOMCMD and CSLOMI when OPTION=APOOUTPUT are described in the DISPLAY macro in the IMS.SDFSMAC data set.

For example, with the CSLOMI request, the QUERY parameter allows you to query all clients that are registered to OM. The clients are returned embedded in \(<cmdclients>\)</cmdclients> tags.

The list of XML tags and the descriptions of each tag are provided in "XML tags returned as CSL OM responses" on page 263.
Chapter 5. Writing a CSL ODBM client

You can write your own ODBM clients that register with Open Database Manager (ODBM) and use the CSLDMI interface to pass DL/I calls to databases that are managed by IMS DB in DBCTL and DB/TM systems within an IMSplex.

IMS Connect, which provides TCP/IP connection management and routing services for the IMS Universal drivers, is an example of an ODBM client. IMS Connect and the IMS Universal drivers are delivered with IMS and you do not need to code any CSL ODBM requests to use them with ODBM.

Other ODBM clients can be application servers, such as WebSphere® Application Server for z/OS or DB2® for z/OS, that run application programs that access IMS databases through the IMS ODBM API.

To write an ODBM client, you can use the set of client requests provided by ODBM. These requests allow the ODBM client, a z/OS application program written in the assembler programming language, to access IMS databases in an IMSplex that are managed by IMS DB systems configured for the IMS DBCTL or DB/TM environments. An example of an ODBM client is IMS Connect.

ODBM clients submit CSLDMI requests to register with ODBM, interact with IMS databases, and manage syncpoint processing for local or global transactions.

The ODBM CSLDMI API uses the IMS ODBA interface to communicate with IMS DB and therefore supports only the DL/I calls that the ODBA interface supports. ODBM clients pass the DL/I calls to IMS DB by using the ODBMCI function of the CSLDMI API.

Sequence of ODBM client requests

Some requests to Open Database Manager (ODBM) from an ODBM client must be issued in a particular sequence, such as when enabling or disabling communication with ODBM.

An ODBM client issues SCI and ODBM requests to request ODBM services. Some of the requests must follow a particular sequence. Other requests can be issued multiple times, in any order, based on the processing requirements of the client.

Before an ODBM client can issue ODBM requests, it must register with SCI and all active ODBMs in the IMSplex.

The following table shows the basic sequence of requests that an ODBM client issues. The CSLSCREG, CSLSCRDY, and CSLDMREG requests must be issued in the order shown. The CSLSCBFR, CSLDMDRG, and CSLSCDRG requests must also be issued in the order shown. The sequence order of the CSLDMI requests can vary depending on the requirements of the ODBM client and syncpoint processing.

“Registering an ODBM client” on page 107

Related reference:
“CSLDMREG: ODBM client registration request” on page 157

CSL ODBM client requests

ODBM clients submit requests to register with ODBM, interact with IMS databases, and commit or backout database updates.

CSLDMDRG: ODBM client deregistration request

The CSLDMDRG request deregisters an ODBM client with ODBM.

An ODBM client issues the CSLDMDRG request when the ODBM client is finished sending ODBA calls through ODBM. The deregister request cleans up the internal control blocks that ODBM stores for the ODBM client.

CSLDMDRG DSECT syntax

Use the DSECT function of a CSLDMDRG request to include equate (EQU) statements in your program for the CSLDMDRG parameter list length and return and reason codes.

CSLDMDRG request protocol syntax
CSLDMDRG parameters

The CSLDMDRG parameters specify the ODBM values required for deregistration with ODBM.

The addresses can be specified as either a symbol or a register from 2 to 12.

The CSLDMDRG request includes the following parameters:

- **ODBMNAME**
  - `symbol`
  - `(r2-r12)`
  - (Required) - Specifies the 8-byte ODBM name to which to send the command deregistration request.
  
  If the value of ODBMNAME is specified as a symbol, the symbol must be the label of the ODBM field. If the value of ODBMNAME is specified as a register, the register must contain the address of the ODBM name field.

- **PARM**
  - `symbol`
  - `(r1-r12)`
  - (Required) - Specifies the CSLDMDRG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by DDG_PARMLN.
  
  If the value of PARM is specified as a symbol, the symbol must denote the start of the parameter list storage. If the value of PARM is specified as a register, the register must contain the address of the parameter list.

- **RETCODE**
  - `symbol`
  - `(r2-r12)`
  - (Required) - Specifies a 4-byte field to receive the return code on output.

  ODBM return codes are defined in the CSLDRR. SCI return codes are defined in CSLSRR.

  The return code can be from ODBM (CSLDMDRG) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. All return codes contain the SCI member type indicator for either SCI or ODBM in the high order byte (X'01' for SCI and X'04' for ODBM).

- **RSNCODE**
  - `symbol`
  - `(r2-r12)`
  - (Required) - Specifies a 4-byte field to receive the reason code on output.

  ODBM reason codes are defined in the CSLDRR. SCI reason codes are defined in CSLSRR.

- **SCITOKEN**
  - `symbol`
  - `(r2-r12)`
  - (Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCRE6 FUNC=REGISTER request.

CSLDMDRG return and reason codes

The return and reason codes in the following table can be returned on a CSLDMDRG macro request.
Table 40. CSLMDRG return and reason codes

<table>
<thead>
<tr>
<th>Return code</th>

<td>X'00004004'</td>
<td>The client is not registered.</td>
</tr>
<tr>
<td>X'00004020'</td>
<td>X'00004020'</td>
<td>The parameter list version of the parameter list specified on the PARM= parameter is invalid.</td>
</tr>
</tbody>
</table>

**CSLDMI: ODBM application program interface**

Application programs written in assembler and running on z/OS can access IMS databases managed by IMS DB in DBCTL and DB/DC systems in an IMSplex by using the CSL Open Database Manager (ODBM) CSLDMI API.

The CSLDMI API supports all of the DL/I calls supported by the IMS ODBA interface, global and local transaction processing, and security.

Prior to issuing the CSLDMI request, the ODBM client must first register with ODBM by issuing the CSLDMREG request.

The CSLDMI API includes the following function calls:

**BACKOUT**
Backs out a local unit of work for local transactions. A local unit of work consists of a single APSB call that has work, such as DL/I calls, associated with the APSB thread.

**COMMIT**
Commits a local unit of work for local transactions. A local unit of work consists of a single APSB call that has work, such as DL/I calls, associated with the APSB thread.

**DSECT**
Includes equate (EQU) statements in an application program for the length of a CSLDMI parameter list and for CSLDMI return and reason codes.

**ODBMCI**
To issue DL/I calls to IMS databases, use the ODBMCI function. DL/I calls are passed to IMS by using the DLIFUNC parameter of the ODBMCI function.

Prior to issuing an ODBMCI function call, you must ensure that the AIB fields are coded appropriately for the DL/I calls that are being passed in the DLIFUNC parameter.

The following parameters are specific to the ODBMCI function and cannot be specified on other CSLDMI function calls:

- AIB
- CLIENTID
- CLIENTIDLEN
- CTXTOKEN
- DLIFUNC
- GROUPNAME=
- GROUPNAMELEN=
- IOAREA
- IOAREALEN
- PCB
READYSYNCPT
Prepares for syncpoint processing for each of the multiple APSB calls within a global unit of work.

The READYSYNCPT function of the CSLDMI API must be called before initiating syncpoint processing for global transactions, such as those that contain multiple APSB threads within a single unit of work. The ODBM client must issue FUNC=READYSYNCPT for each APSB that is represented by an APSBTOKEN in a global unit of work (UOW). This pertains to the URTOKEN parameter. See the URTOKEN parameter for more description.

Before initiating syncpoint processing, the caller must issue FUNC=READYSYNCPT for each APSB call in the global UOW. CSLDMI uses an APSB token (APSBTOKEN) to represent each APSB call.

CSLDMI FUNC=ODBMCI syntax
The CSLDMI parameters specify the ODBM values required for communicating with ODBM and accessing IMS databases.

The addresses can be specified as either a symbol or a register from 2 to 12.

Parameters that are supported only when the ODBMCI function is specified are noted in the description of the parameters. Parameters that are not noted as being supported by ODBMCI only, can be specified on all CSLDMI functions other than DSECT.

The following parameters can be specified on one or more functions of the CSLDMI API:

**AIB=symbol | (r2-r12)**

(Required) - Specifies the address of the application interface block (AIB). The AIB parameter is required on both input to and output from ODBM. This parameter is supported only on the ODBMCI function call.

When the SCI message protocol (PROTOCOL=MSG) is specified on a CSLDMI request, ODBM returns the address of the AIB in the DDIR_DMIRAIBPTR field of the ODBM directive parameter list, which is mapped by the CSLDMIDIR macro.

Prior to issuing CSLDMI FUNC=ODBMCI, the AIB fields required by each DL/I call being passed on the DLIFUNC parameter must be set. The fields of
the AIB are mapped by the DFSAIB macro and described in “Specifying the AIB mask for ODBA applications” in IMS Version 13 Application Programming.

If the AIB is specified as a register, the register must contain the address of the AIB area. If the AIB is specified as a symbol, the symbol must be the label of the AIB area.

**APSBTOKEN=symbol | (r2-r12)**
(Required) - Specifies an address for a 16-byte ODBM APSB token. An APSB token is returned by CSLDMI on the initial APSB thread request and is required on all subsequent calls targeted to this thread.

On an APSB request, APSBTOKEN specifies the address of the field to receive the token from ODBM. The length of APSBTOKEN field must be 16 bytes as defined by DMI_APSBTKNLEN in the CSLDMI macro.

For all subsequent requests associated to this thread, APSBTOKEN specifies the address of this 16-byte token.

When the SCI message protocol (PROTOCOL=MSG) is specified on a CSLDMI request, ODBM returns the address of the APSB token in the DDIR_DMIAPSBTPTTR field of the ODBM directive parameter list, which is mapped by the CSLDMDIR macro.

If the APSBTOKEN parameter is specified as a register, the register must contain the address of the token field. If the APSBTOKEN parameter is specified as a symbol, the symbol must be the label of the token field.

**CLIENTID=symbol | (r2-r12)**
(Optional) - Specifies the end user client application ID as defined by the end user client.

If the CLIENTID parameter is specified as a register, the register must contain the address of the client ID field. If the CLIENTID parameter is specified as a symbol, the symbol must be the label of the client ID field.

**CLIENTIDLEN=symbol | (r2-r12)**
(Required when CLIENTID is specified) - Specifies the length of the client ID.

If the CLIENTIDLEN parameter is specified as a register, the register must contain the length of the client ID. If the CLIENTIDLEN parameter is specified as a symbol, the symbol must be the label of a fullword containing the length of the client ID.

**CTXTOKEN=symbol | (r2-r12)**
(Optional) - Specifies a 16-byte private context token obtained by calling the Begin_Context service (CTXBEGC) of the z/OS recoverable resource management services (RRMS) context services. This parameter is supported only on the ODBMCI function call.

CTXTOKEN can be used to setup a global unit of work made up of multiple APSB calls within one commit scope on a single LPAR. When specified, each initial APSB call within the global unit of work must include the same CTXTOKEN.

The ODBM client must ensure that the private context token specified on CTXTOKEN has been disassociated from any dispatchable unit, such as a TCB, prior to passing the private context token to ODBM. The ODBM client is also responsible for initiating syncpoint processing using the appropriate z/OS Resource Recovery Services services, such as ATRAPRP, ATRACMT, ATRABCK, ATRCMIT, ATRBACK, and so forth.
The ODBM client must establish an RRS unit of work identifier (UWID) if needed. Usually, the UWID is an XID. ATRSWID2 is used to set a work identifier. The UWID is set based on the context token specified on this CTXTOKEN parameter.

If the CTXTOKEN parameter is specified as a register, the register must contain the address of the private context token field. If the CTXTOKEN parameter is specified as a symbol, the symbol must be the label of the private context token field.

**DLIFUNC**=**symbol** | *(r2-r12)*

(Required) - Specifies the 4-byte DL/I call. Any DL/I call that is supported by the Open Database Access (ODBA) callable interface can be specified. This parameter is supported only on the ODBMCI function call.

Prior to issuing CSLDMI FUNC=ODBMCI DLIFUNC, the AIB fields required by each DL/I call being passed on the DLIFUNC parameter must be set. The fields of the AIB are mapped by the DFSAIB macro and described in “Specifying the AIB mask for ODBA applications” in IMS Version 13 Application Programming.

If the DLIFUNC parameter is specified as a register, the register must contain the address of the DLI function code. If the DLIFUNC parameter is specified as a symbol, the symbol must be the label of the DLI function code.

**ECB**=**symbol** | *(r2-r12)*

(Optional) - Specifies an MVS™ event control block (ECB) that is used for asynchronous requests. When the request is complete, the ECB specified is posted.

If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the ODBM client that invokes the CSLDMI macro must invoke the z/OS WAIT macro (or equivalent) after receiving control from CSLDMI before using or examining any data returned by CSLDMI, including the RETCODE and RSNCODE fields.

If the ECB parameter is specified as a register, the register must contain the address of the ECB. If the ECB parameter is specified as a symbol, the symbol must denote the start of the ECB storage.

**GROUPNAME**=**symbol** | *(r2-r12)*

(Optional) - Specifies a group name for RACF or an equivalent security product. The group name pertains to the APSB call only (DLIFUNC=APSB) and is ignored for all other DL/I calls.

If the GROUPNAME parameter is specified as a register, the register must contain the address of the group name field. If the GROUPNAME parameter is specified as a symbol, the symbol must be the label of the group name field.

**GROUPNAMELEN**=**symbol** | *(r2-r12)*

(Required when GROUPNAME is specified) - Specifies the length of the group name.

If the GROUPNAMELEN parameter is specified as a register, the register must contain the length of the group name. If the GROUPNAMELEN parameter is specified as a symbol, the symbol must be the label of a fullword containing the length of the group name.

**IOAREA**=**symbol** | *(r2-r12)*

(Conditionally required) - Specifies an I/O area that is used for the input or output data related to a database DL/I call. The IOAREA and IOAREALEN parameters are required only when a DL/I call that requires input data or that
returns output data is specified on the DLIFUNC parameter. This parameter is supported only on the ODBMCI function call.

When the SCI message protocol (PROTOCOL=MSG) is specified on a CSLDMI request, ODBM returns the address of the I/O area in the DDIR_DMIRIOAPT field of the ODBM directive parameter list, which is mapped by the CSLDMDIR macro.

If the IOAREA parameter is specified as a register, the register must contain the address of the I/O area. If the IOAREA parameter is specified as a symbol, the symbol must be the label of the I/O area.

**IOAREALEN=symbol | (r2-r12)**

(Conditionally required) - Specifies the length of the I/O area specified by the IOAREA parameter. The IOAREA and IOAREALEN parameters are required only when a DL/I call that requires input or that returns output is specified on the DLIFUNC parameter. This parameter is supported only on the ODBMCI function call.

The length specified on the IOAREALEN parameter must also be specified on the AIBOALEN field of the AIB mask. For information about the AIB mask, see Specifying the AIB mask (Application Programming).

If the IOAREALEN parameter is specified as a register, the register must contain the length of the I/O area. If the IOAREALEN parameter is specified as a symbol, the symbol must be the label of a fullword containing the length of the I/O area.

**ODBMNAME=symbol | (r2-r12)**

(Required) - Specifies the 8-byte ODBM name to which to the CSLDMI request is to be sent.

If the ODBMNAME parameter is specified as a symbol, the symbol must be the label of the ODBM field. If the ODBMNAME parameter is specified as a register, the register must contain the address of the ODBM name field.

**PARM=symbol | (r2-r12)**

(Required) - Specifies the address CSLDMI parameter list. The length of the parameter list must be at least as long as the value assigned to DMI_PARMLN in the CSLDMI macro.

Use CSLDMI FUNC=DSECT to include equate (EQU) statements in your application program for the length of the CSLDMI parameter list.

If the value of PARM is specified as a register, the register must contain the address of the parameter list. If the value of PARM is specified as a symbol, the symbol must denote the start of the parameter list storage.

**PCB=symbol | (r2-r12)**

(Optional) - An output parameter that specifies the address of a fullword storage area to receive the address of the program communication block (PCB) returned by IMS after processing a DL/I call. The PCB contains the status codes related to a DL/I call and other fields. This parameter is supported only on the ODBMCI function call.

The PCB storage is not preallocated by the caller. Upon return from the request, the address in the PCB parameter contains the address of a storage buffer that contains the PCB. After the ODBM client is finished with the PCB, the ODBM client must release the PCB storage buffer by issuing the SCI request CSLSCBFR FUNC=RELEASE.
When the SCI message protocol (PROTOCOL=MSG) is specified on a CSLDMI request, ODBM returns the address of the PCB storage in the DDIR_DMIRPCBPTR field of the ODBM directive parameter list, which is mapped by the CSLDMDIR macro.

If specified as a register, the register must contain the address of a fullword to contain the address of the PCB. If specified as a symbol, the symbol must be the label of a fullword to contain the address of the PCB.

PCBLEN=symbol | (r2-r12)  
(Conditionally required) - Specifies the length of the PCB returned by DL/I call processing. The PCBLEN parameter is required when the PCB parameter is specified. This parameter is supported only on the ODBMCI function call.

If specified as a register, the register must contain the address of a fullword to contain the length of the PCB. If specified as a symbol, the symbol must be the label of a fullword to contain the length of the PCB.

PROTOCOL=MSG | RQST  
(Optional) - Specifies the SCI protocol for sending the request to ODBM.

   MSG  
   Specifies that CSLDMI sends input requests to ODBM by using the SCI message protocol, which uses a one-way send of the data to the other IMSplex members and does not support output parameters. The ODBM client does not wait for output from ODBM and any output generated by the requests that use the MSG protocol is handled asynchronously.

   RQST  
   Specifies that CSLDMI sends input requests to ODBM by using the SCI request protocol. The SCI request protocol supports both input and output parameters. The ODBM client waits for output from ODBM and process it synchronously. RQST is the default.

RETCODE=symbol | (r2-r12)  
(Required) - Specifies a 4-byte field to receive the return code on output. ODBM return codes are defined in the CSLDRR. SCI return codes are defined in CSLSRR.

The return code can be from ODBM (CSLDMI) or SCI (CSLSCMSG or CSLSCRQS). If an ECB is specified, the value of RETCODE is not valid until the ECB is posted. All return codes contain the SCI-member-type indicator for either SCI or ODBM in the high order byte (X’01’ for SCI or X’04’ for ODBM).

RQSTTKN1=symbol | (r2-r12)  
(Conditionally optional) - Specifies a 16-byte user-generated request token that correlates an output response to its associated input request for asynchronous processing. ODBM returns the address of this token in the DDIR_DMIQT1PTR field of the ODBM directive parameter list that is mapped by CSLDMDIR.

RQSTTKN1 is supported only when the SCI message protocol is specified by PROTOCOL=MSG.

If specified as a register, the register must contain the address of the request token field. If specified as a symbol, the symbol must be the label of the request token field. The request token field must be 16 bytes in length, left justified, and padded with blanks if necessary.
RSNCODE=\texttt{symbol} \mid \texttt{(r2-r12)}

(Required) - Specifies a 4-byte field to receive the reason code on output. ODBM reason codes are defined in the CSLDRR macro. SCI reason codes are defined in CSLSRR.

SCITOKEN=\texttt{symbol} \mid \texttt{(r2-r12)}

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

If the SCITOKEN parameter is specified as a register, the register must contain the address of the SCI token field. If the SCITOKEN parameter is specified as a symbol, the symbol must be the label of the SCI token field.

SECTKNLEN=\texttt{symbol} \mid \texttt{(r2-r12)}

(Conditionally required) - Specifies the length of the security token. The SECTKNLEN parameter is required when the SECTOKEN parameter is specified. This parameter is supported only on the ODBMCI function call.

If the SECTKNLEN parameter is specified as a register, the register must contain the length of the security token. If the SECTKNLEN parameter is specified as a symbol, the symbol must be the label of a fullword containing the length of the security token.

SECTOKEN=\texttt{symbol} \mid \texttt{(r2-r12)}

(Conditionally optional) - Specifies the address of a variable length security token that is used for security checking by RACF or an equivalent security product. The security token applies only to the APSB DL/I call that is specified by DLIFUNC=APSB. The security token is ignored for all other DL/I calls. This parameter is supported only on the ODBMCI function call. This security token is used only if the client address space is an authorized caller. If the client address space is unauthorized, the user ID is obtained automatically from z/OS control blocks.

The security token must be a security object. For example, if RACF is used, the security token must be a RACO (RACF Object). ODBM invokes RACROUTE REQUEST=VERIFY,ENVIR=CREATE with ENVIRIN= to establish a security environment with a RACF accessor environment element (ACEE) for the APSB thread. IMS uses the ACEE during ODBA or RAS security authorization for the PSB.

If the SECTOKEN parameter is specified as a register, the register must contain the address of the security token field. If the SECTOKEN parameter is specified as a symbol, the symbol must be the label of the security token field.

SSAn=\texttt{symbol} \mid \texttt{(r2-r12)}

(Optional) - Specifies the segment search arguments (SSAs) for a DL/I call. A maximum of 15 SSAs can be specified: SSA1 through SSA15. This parameter is supported only on the ODBMCI function call.

If the parameters SSA1 through SSA15 are specified as registers, each register must contain the address of an SSA. If the parameters SSA1 through SSA15 parameters are specified as symbols, each symbol must be the label of a fullword that contains the address of an SSA.

SSAnLEN=\texttt{symbol} \mid \texttt{(r2-r12)}

(Conditionally required) - Specifies the length of the corresponding SSA list area. For every SSAn parameter specified, a corresponding SSAnLEN parameter is required, specified as SSA1LEN up through SSA15LEN. This parameter is supported only on the ODBMCI function call.
If the parameters SSA1LEN through SSA15LEN are specified as registers, the registers must contain the length of the SSA list areas. If the parameters SSA1LEN through SSA15LEN are specified as symbols, the symbols must be the labels of a fullword containing the length of the SSA list areas.

URTOKEN=\texttt{symbol} | (r2-r12)  
(Optional) - Specifies a 16-byte RRS parent unit of recovery (UR) token. The token is obtained by calling the RRS Express\_UR\_Interest service (ATREINT5). A URTOKEN is required to setup a global unit of work that spans multiple APSB calls within one commit scope on more than one LPAR. If specified, the same URTOKEN must be included on each initial APSB call within the global unit of work. This parameter is supported only on the ODBMCI function call.

The ODBM client must be a z/OS authorized program running in supervisor state, running with PSW key 0-7, or both and cannot be running in problem state.

The ODBM client is responsible for initiating syncpoint processing by using the appropriate RRS services, such as ATRPRP, ATRACMT, ATRABCK, ATRCMIT, ATRBACK, and so forth. Before initiating syncpoint processing, the ODBM client must issue FUNC=READYSYNCPT for each APSB call in the global UOW. CSLDMI uses an APSB token to represent each APSB call.

If needed, the ODBM client must establish an RRS unit-of-work identifier (UWID). Usually, the UWID is an XID. ATRSWID2 is used to set a UWID. The UWID is based on the parent UR token specified on this URTOKEN parameter.

If the URTOKEN parameter is specified as a register, the register must contain the address of the RRS UR token field. If the URTOKEN parameter is specified as a symbol, the symbol must be the label of the RRS UR token field.

USERID=\texttt{symbol} | (r2-r12)  
(Optional) - Specifies the user ID to be used by RACF or an equivalent security product. Use this parameter only if your client address space has been authorized for this request. If your client is not authorized, the user ID is obtained automatically from z/OS control blocks. The user ID pertains to the APSB call only (DLIFUNC=APSB) and is ignored for all other DL/I calls.

If the USERID parameter is specified as a register, the register must contain the address of the user ID field. If the USERID parameter is specified as a symbol, the symbol must be the label of the user ID field.

USERIDLEN=\texttt{symbol} | (r2-r12)  
(Required when USERID is specified) - Specifies the length of the user ID.

If the USERIDLEN parameter is specified as a register, the register must contain the length of the user ID. If the USERIDLEN parameter is specified as a symbol, the symbol must be the label of a fullword containing the length of the user ID.

**CSLDMI return and reason codes**

The return and reason codes in the following table can be returned on a CSLDMI macro request.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>

CSLDMREG: ODBM client registration request

The CSLDMREG request registers an ODBM client with ODBM.

With the CSLDMREG request, an ODBM client, such as WebSphere Application Server for z/OS or DB2 for z/OS, can register with an instance of ODBM.

The CSLDMREG request registers an application program with ODBM as an ODBM client. The register command must be the first request that a client issues to ODBM.

Use the CSLSCQRY request to obtain the names of all ODBMs in the IMSplex.

CSLDMREG DSECT syntax

Use the DSECT function of a CSLDMREG request to include equate (EQU) statements in your program for the CSLDMREG parameter list length and return and reason codes.

```
CSLDMREG FUNC=DSECT
```

Request protocol syntax

```
CSLDMREG FUNC=REGISTER ECB=ecb ODBMNAME=odbmname OUTLEN=outlen

OUTPUT=output PARM=parm RETCODE=returncode

RSNCODE=reasoncode SCITOKEN=scitoken
```

CSLDMREG parameters

The CSLDMREG parameters specify the ODBM values required for registration with ODBM.

The addresses can be specified as either a symbol or a register from 2 to 12.

The CSLDMREG command includes the following parameters:

- **ECB**=symbol
  - (Optional) - Specifies the address of a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLDMREG before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).
  
  If the value of ECB is specified as a symbol, the symbol must denote the start of the ECB storage. If the value of ECB is specified as a register, the register must contain the address of the ECB.

- **ODBMNAME**=symbol
**ODBMNAME**=\( (r_2-r_{12}) \)  
(Optional) - Specifies the 8-byte ODBM name to which to send the command registration request.

Either the ODBMNAME parameter or the RETNAME parameter, but not both, must be specified on a CSLDMREG request.

Use the ODBMNAME parameter to connect the ODBM client to a specific, known instance of ODBM.

If the value of ODBMNAME is specified as a symbol, the symbol must be the label of the ODBM field. If the value of ODBMNAME is specified as a register, the register must contain the address of the ODBM name field.

**OUTLEN**=\( \text{symbol} \)  
**OUTLEN**=\( (r_2-r_{12}) \)  
(Required) - Specifies a 4-byte field to receive the length of the output returned by the CSLDMREG request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

If no output is built, the output length is zero, as is the case when an error is detected before building the output.

If the value of OUTLEN is specified as a register, the register must contain the address of the output length field. If the value of OUTLEN is specified as a symbol, the symbol must be the label of the output length field.

**OUTPUT**=\( \text{symbol} \)  
**OUTPUT**=\( (r_2-r_{12}) \)  
(Required) - Specifies a 4-byte field to receive the variable length output returned by the CSLDMREG request. The output length is returned in the OUTLEN= field.

If no output is built, the output address is zero, as is the case when an error is detected before building the output.

The CSLDREGO macro maps the output that is returned. The output buffer contains the ODBM version, count of the aliases, and a list of the 4-byte alias names.

The output buffer is not preallocated by the caller. Upon return from the request, this word contains the address of a buffer containing the update output.

After the ODBM client no longer needs the buffer storage, the ODBM client must release the storage by issuing the CSLSCBFR FUNC=RELEASE request.

If the value of OUTPUT is specified as a register, the register must contain the address of a field to contain the output address. If the value of OUTPUT is specified as a symbol, the symbol must be the label of a field to contain the output.

**PARM**=\( \text{symbol} \)  
**PARM**=\( (r_1-r_{12}) \)  
(Required) - Specifies the address of the CSLDMREG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by DREG_PARMNL.

If the value of PARM is specified as a symbol, the symbol must denote the start of the parameter list storage. If the value of PARM is specified as a register, the register must contain the address of the parameter list.

**RETCODE**=\( \text{symbol} \)
RETCODE=\(r2-r12\)

(Required) - Specifies a 4-byte field to receive the return code on output. ODBM return codes are defined in the CSLDRR. SCI return codes are defined in CSLSRR.

The return code can be from ODBM (CSLDMREG) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. All return codes contain the SCI member type indicator for either SCI or ODBM in the high order byte (X'01' for SCI and X'04' for ODBM).

If the value of RETCODE is specified as a symbol, the symbol must be the label of the return code field. If the value of RETCODE is specified as a register, the register must contain the address of the return code field.

RETNAME=\textit{symbol}\n
RETNAME=\(r2-r12\)

(Optional) - Specifies the eight-byte output field to receive the ODBM name. This is the CSL member name of the target address space to which SCI sent the request.

Either the RETNAME parameter or the ODBMNAME parameter, but not both, must be specified on a CSLDMREG request.

Use the RETNAME parameter if you do not know the name of an ODBM instance or if the ODBM client does not require a connection to a specific instance of ODBM. When RETNAME is specified, SCI connects to any available instance of ODBM and returns the name of that ODBM in the RETNAME output field.

If the value of OUTPUT is specified as a register, the register must contain the address of a field to contain the output address. If the value of OUTPUT is specified as a symbol, the symbol must be the label of a field to contain the output.

RSNCODE=\textit{symbol}\n
RSNCODE=\(r2-r12\)

(Required) - Specifies a 4-byte field to receive the reason code on output. ODBM reason codes are defined in the CSLDRR. SCI reason codes are defined in CSLSRR.

If the value of RSNCODE is specified as a symbol, the symbol must be the label of the reason code field. If the value of RSNCODE is specified as a register, the register must contain the address of the reason code field.

SCITOKEN=\textit{symbol}\n
SCITOKEN=\(r2-r12\)

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

If the value of SCITOKEN is specified as a register, the register must contain the address of the SCI token field. If the value of SCITOKEN is specified as a symbol, the symbol must be the label of the SCI token field.

**CLSDMREG return and reason codes**

The return and reason codes in the following table can be returned on a CLSDMREG macro request. The hexadecimal value 04 represents the SCI member type for ODBM.
<table>
<thead>
<tr>

Chapter 6. Writing a CSL OM client

These topics describe the client requests and directives for writing an OM client.

CSL OM command processing client requests

The following topics describe the requests that are made by command processing clients.

If you are writing your own command processing client, ensure that the access authority you provide on the RACF PERMIT command matches the access authority with which the command is registered.

Related tasks:
“Registering an OM command processing client” on page 108

CSLOMBLD: command registration build

With the CSLOMBLD request, you can build the command registration list that is passed to OM on the CSLOMREG request.

This list identifies the commands for which the IMS system can be called. The list contains a set of statements starting with a CSLOMBLD FUNC=BEGIN statement and ending with a CSLOMBLD FUNC=END statement.

Any number of CSLOMBLD FUNC=DEFVRB statements can be provided, each one defining the command verb. Following each DEFVRB statement are CSLOMBLD FUNC=DEFKEY statements, which identify keywords valid for the previously defined command verb.

The set of CSLOMBLD statements can be defined either in a separate data-only assembler module, or in a static data section of an executable assembler module. Refer to the documentation in the CSLOMBLD macro.

CSLOMBLD is used to build the command registration list; it does not have an input parameter list.

CSLOMBLD syntax

CSLOMBLD BEGIN

Use the BEGIN function statement to identify the beginning of the set of command statements.

CSLOMBLD DEFVRB

Use the DEFVRB function statement to identify a command that the OM client or IMS system will support. You can specify a short form of the command verb.
**CSLOMBLD DEFKEY**

Use the DEFKEY function statement to identify a keyword that is valid for the previously defined command. You can also specify command routing and required RACF authorization with this statement.

```
CSLOMBLD FUNC=DEFKEY KEYW=keyword ROUTE=ANY|ALL SEC=READ|UPDATE
```

**CSLOMBLD DEFGMR**

Use the DEFGMR function statement to identify the beginning of the statements that describe the output parsing grammar.

**Note:** This function is for internal IBM use only.

```
CSLOMBLD FUNC=DEFGMR
```

**CSLOMBLD ENDGMR**

Use the ENDGMR function statement to designate the end of the statements that describe the output parsing grammar.

**Note:** This function is for internal IBM use only.

```
CSLOMBLD FUNC=ENDGMR
```

**CSLOMBLD END**

Use the END function statement to designate the end of the list of command statements.

```
CSLOMBLD FUNC=END
```

**CSLOMBLD parameters**

- **KEYW=** *keyword*
  
  Specifies a valid keyword for the command verb that immediately precedes this parameter. For a null keyword, use blanks; for example, 'KEYW= '. This parameter is required for FUNC=DEFKEY.

- **NORM=** *shortverbname*
  
  Specifies the short form of the command being defined. This parameter is required for FUNC=DEFVRB.

- **ROUTE=** *ANY | ALL*
  
  Specifies the override routing for the command being defined. This parameter is required for FUNC=DEFKEY.

- **SEC=** *READ | UPDATE*
  
  Specifies the required RACF authorization for KEYW. This parameter is required for FUNC=DEFKEY.
**VERB=vername**

Specifies the long form of the command being defined. This parameter is required for FUNC=DEFVRB.

**CSLOMBLD example**

The following shows an example of a set of CSLOMBLD statements.

```
CSLOMBLD FUNC=BEGIN
CSLOMBLD FUNC=DEFVRB,VERB=ACTIVATE,NORM=ACT
CSLOMBLD FUNC=DEFKEY,KEYW=LINK,SEC=UPDATE
CSLOMBLD FUNC=DEFKEY,KEYW=NODE,SEC=UPDATE
CSLOMBLD FUNC=END
```

**Overriding CSL OM command routing with the ROUTE parameter**

CSLOMBLD allows the command processing client to override the routing that you specify when you enter a command. There are a few commands that specify command routing overrides. OM overrides command routing when two command processing clients specify different routing overrides for the same command if:

- At least one command processing client specifies an override of ROUTE=ALL, then OM routes the command to all registered command processing clients.
- At least one command processing client specifies an override of ROUTE=ANY, and no command processing client has specified ROUTE=ALL, then OM routes the command to one of the registered command processing clients.
- No command processing clients have specified an override of ROUTE=ALL or ROUTE=ANY, then OM routes the command as specified by the user that entered the command.

When an OM command has a ROUTE parameter, IMS chooses the highest level IMS in the route list as the command master. For example, in an IMSplex configuration that includes an IMS Version 13 system with an IMS Version 13 CQS, and another IMS system with a previous version SCI, if an INIT OLC command (which is a ROUTE=ANY command) is issued, the IMS Version 13 system is selected as the command master.

For a list of the commands that can be issued with the ROUTE parameter, see [Commands and keywords supported by the OM API (Commands)](Commands).

**Related reference:**

- [/SECURE command](Commands)
- “CSOMREG: command registration request” on page 168

**CSLOMDRG: command deregistration request**

With the CSLOMDRG request, a command processing client like the IMS control region tells OM that it no longer wants to process commands. All client information from the OM command registration table is removed and OM stops sending further commands to the client.

**CSLOMDRG syntax**

`DSECT syntax`
Use the DSECT function of a CSLOMDRG request to include equate (EQU) statements in your program for the CSLOMDRG parameter list length and return and reason codes.

Request protocol syntax

CSLOMDRG—FUNC=DSECT

CSLOMDRG parameters

**PARM=**symbol

*PARM=(r2-r12)*

(Required) - Specifies the CSLOMDRG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by ODRG_PARM LN.

**RETCODE=**symbol

*RETCODE=(r2-r12)*

(Required) - Specifies a 4-byte field to receive the return code on output. Possible return codes are described in the following table. The return code can be from OM (CSLOMDRG) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. The value of the high-order byte in the return code identifies whether SCI (X'01') or OM (X'02') provided the return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

**RSNCODE=**symbol

*RSNCODE=(r2-r12)*

(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=**symbol

*SCITOKEN=(r2-r12)*

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

CSLOMDRG return and reason codes

The return and reason codes in following table can be returned on a CSLOMDRG macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
</tbody>
</table>
CSLOMOUT: unsolicited output request

The CSLOMOUT request is issued by a command processing client that wants to send a message indirectly in response to a command. The message can be additional information as a result of a command issued after the initial command response is returned to OM, or an informational message as a result of an event in the system. OM sends the unsolicited message to the OM Output user exit.

CSLOMOUT syntax

DSECT syntax

Use the DSECT function of a CSLOMOUT request to include equate (EQU) statements in your program for the CSLOMOUT parameter list length and return and reason codes.

Request protocol syntax

CSLOMOUT parameters

CMD=symbol
CMD=(r2-r12)  
(Optional) - Specifies the command input buffer. This can be any IMS command that can be specified through the OM API. This parameter represents the original command input.

CMDLEN=symbol
CMDLEN=(r2-r12)  
(Optional) - Specifies the length of the command input buffer.

MSGDATA=symbol
MSGDATA=(r2-r12)  
(Required) - Specifies the command response message buffer.

MSGDATALEN=symbol
MSGDATALEN=(r2-r12)  
(Required) - Specifies the length of the command response message buffer.

OMNAME=symbol
OMNAME=(r2-r12)  
(Optional) - Specifies the 8-byte OM name to which to send the unsolicited output message when the message is an asynchronous response to a command.

RQSTTKN=symbol
RQSTTKN=(r2-r12)
(Optional) - Specifies the 32-byte request token that was passed to the command processing client on an OM command directive. This represents the RQSTTKN1 and RQSTTKN2 fields that are entered on either or both the CSLOMI and CSLOMCMDD requests.

PARM=symbol
PARM=(r2-r12)
(Required) - Specifies the CSLOMOUT parameter list. The length of the parameter list must be equal to the parameter list length EQU value that is defined by OOUT_PARMLN.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. Possible return codes are described in the following table.

The return code can be from OM (CSLOMOUT) or SCI (CSLSCMSG or CSLSCREQ). If ECB is specified, the RETCODE is not valid until the ECB is posted. The value of the high-order byte in the return code identifies whether SCI (X'01') or OM (X'02') provided the return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

RSNCODE=symbol
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

SCITOKEN=symbol
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

**CSLOMOUT return and reason codes**

The return and reason codes in the following table can be returned on a CSLOMOUT macro request. The following table lists the return and reason codes that can be returned on a CSLOMI macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
</tbody>
</table>

**CSLOMRDY: ready request**

With the CSLOMRDY request, command processing clients like the IMS control region notify OM that they are ready to process commands. OM does not send commands to a client until this request is processed.

**CSLOMRDY syntax**

```CBSL
CSLOMRDY DSECT syntax
```
Use the DSECT function of a CSLOMRDY request to include equate (EQU) statements in your program for the CSLOMRDY parameter list length and return and reason codes.

►►CSLOMRDY—FUNC=DSECT◄◄

**CSLOMRDY request protocol syntax**

►►CSLOMRDY—FUNC=READY—OMNAME=omname—MASTER=NO|YES—PARM=parm—RETCODE=returncode—RSNCODE=reasoncode—SCITOKEN=scitoken◄◄

**CSLOMRDY parameters**

**MASTER=NO**
**MASTER=YES**

(Optional) - Specifies whether or not the client should be chosen as the command master. If a client specifies MASTER=YES, OM can select that client to be the command master. If the client specifies MASTER=NO, OM selects it to be the command master only if no other client has specified MASTER= YES.

**OMNAME=symbol**  
**OMNAME=(r2-r12)**

(Optional) - Specifies the 8-byte OM name to which to send the command ready request. If an OM name is not specified, the ready request is sent to all OM address spaces registered in the IMSplex.

**PARM=symbol**  
**PARM=(r2-r12)**

(Required) - Specifies the CSLOMRDY parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by ORDY_PARMLN.

**RETCODE=symbol**  
**RETCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the return code on output. Possible return codes are described in the following table.

The return code can be from OM (CSLOMRDY) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. The value of the high-order byte in the return code identifies whether SCI (X’01’) or OM (X’02’) provided the return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

**RSNCODE=symbol**  
**RSNCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=symbol**  
**SCITOKEN=(r2-r12)**

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.
CSLOM RDY return and reason codes

The following table lists the return and reason codes that can be returned on a CSLOM RDY macro request. Also included is the meaning of the reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
</tbody>

Related concepts:

[CSL OM command routing (System Administration)]

CSLOMREG: command registration request

With the CSLOMREG request, a command processing client like the IMS control region can register commands with an OM. The registration tells OM which commands that a client can process.

CSLOMREG must be the first request that a command processing client issues to OM. A command processing client must register with all OM address spaces in the IMSplex. If a client is registered with only one OM in an IMSplex, and that OM goes down, the client’s commands are not routed to another OM in the IMSplex. Use the CSLSCQRY request to obtain the names of all OMs in the IMSplex. The client must be authorized to issue a CSLOMREG request. This authorization is from SCI, which notifies OM that the client can issue requests.

CSLOMREG syntax

CSLOMREG DSECT syntax

Use the DSECT function of a CSLOMREG request to include equate (EQU) statements in your program for the CSLOMREG parameter list length and return and reason codes.

CSLOMREG request protocol syntax

The syntax for the CSLOMREG request follows.

CSLOMREG parameters

CMDLIST=symbol

168 System Programming APIs
CMDLIST=(r2-r12)
(Required) - Specifies the command definition list.

The command list is built using the CSLOMBLD macro.

CMDLISTLEN=symbol
CMDLISTLEN=(r2-r12)
(Required) - Specifies the length of the command definition list buffer.

ECB=symbol
ECB=(r2-r12)
(Optional) - Specifies the address of a z/OS event control block (ECB) used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLOMREG before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).

OMNAME=symbol
OMNAME=(r2-r12)
(Required) - Specifies the 8-byte OM name to which to send the command registration request.

OUTLEN=symbol
OUTLEN=(r2-r12)
(Optional) - Specifies a 4-byte field to receive the length of the output returned by the CSLOMREG request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.

OUTPUT=outputaddr
OUTPUT=(r2-r12)
(Required) - Specifies a field to receive the variable length output returned by the CSLOMREG request. The output length is returned in the OUTLEN= field.

The output is mapped by the CSLOREGO macro and is built only if there was an error registering one or more commands. The output contains a header and one or more list entries. Refer to the CSLOREGO macro for the output fields.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the update output. It is the caller's responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is finished with the storage. The length of the output is returned in the OUTLEN=field.

PARM=symbol
PARM=(r2-r12)
(Required) - Four-byte input parameter that specifies the address of the storage used by the request to pass the parameters to SCI. The length of the parameter list must be equal to the parameter list length EQU value defined by OREG_PARMLEN.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. Possible return codes are described in the following table.
The return code can be from OM (CSLOMREG) or SCI (CSLSCMSGS or CSLSCQRS). If ECB is specified, the RETCODE is not valid until the ECB is posted. The value of the high-order byte in the return code identifies whether SCI (X'01') or OM (X'02') provided the return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

**RSNCODE=** symbol
**RSNCODE=** (r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=** symbol
**SCITOKEN=** (r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

### CLSOMREG return and reason codes

The return and reason codes in the following table can be returned on a CSLOMREG macro request.

#### Table 46. CLSOMREG return and reason codes

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'0200000C'</td>
<td>X'00000300'</td>
<td>The request might or might not have been processed completely. If the OUTPUT parameter is provided on the request, refer to completion codes in the output buffer for error conditions. Completion codes indicate the reason for the error with the resource name. The completion codes that can be returned are described in the following table</td>
</tr>
<tr>
<td>X'02000010'</td>
<td>X'00004010'</td>
<td>The client that issued the command is not authorized.</td>
</tr>
<tr>
<td>X'00004020'</td>
<td>The parameter list version is invalid.</td>
<td></td>
</tr>
<tr>
<td>X'02000014'</td>
<td>X'00005034'</td>
<td>An OM internal error occurred. OM was unable to obtain storage for the output buffer.</td>
</tr>
<tr>
<td>X'00005038'</td>
<td>An OM internal error occurred. OM was unable to add the VERB block to the command verb hash table during command processing.</td>
<td></td>
</tr>
<tr>
<td>X'0000503C'</td>
<td>An OM internal error occurred. OM was unable to allocate a CLNT block for the client during command processing.</td>
<td></td>
</tr>
</tbody>
</table>

The completion codes in the following table can be returned on a CSLOMREG request. They are returned in the ORGE_CC field of the CSLOREGO macro, which maps the OUTPUT= area if an error occurred during command registration.

#### Table 47. CLSOMREG completion codes

<table>
<thead>
<tr>
<th>Completion Code</th>
<th>Meaning</th>
</tr>

CSLOMRSP: command response request

The CSLOMRSP request is issued by a command processing client in response to a command. Command response information is consolidated and sent to OM.

A command processing client issues the CSLOMRSP request in response to a command. All command response information from an individual command processing client is consolidated by the client and sent to OM in one request. OM consolidates the responses from multiple clients into one response for the automated operator program client.

CSLOMRSP syntax

CSLOMRSP DSECT syntax

Use the DSECT function of a CSLOMRSP request to include equate (EQU) statements in your program for the CSLOMRSP parameter list length and return and reason codes.

```
CSOMRSP FUNC=DSECT
```

CSLOMRSP request protocol syntax

```
CSOMRSP FUNC=RESPOND CMD=cmdinput CMDLEN=cmdinputlen CMDTOKEN=cmdtoken

CMDDATA=cmdhdr CMDDATALEN=cmdhdrlen CMDDATAX=cmddata CMDDATALEN=cmddatalen

MSGDATA=msgdata MSGDATALEN=msgdatalen

PARM=parm OMNAME=omname

RETCODE=returncode RSNCODE=reasoncode RQSTRC=requestrc RQSTRSN=requestrsn

RQSTTKN=requesttoken SCITOKEN=scitoken
```

CSLOMRSP parameters

CMD= symbol

CMD=(r2-r12)

(Optional) - Specifies the command input buffer. This can be any IMS command that can be specified through the OM API.

This parameter is optional; what you provide here will be included in the input tags that are returned as XML output.

CMDDATA= symbol

CMDDATA=(r2-r12)

(Optional) - Specifies the command response data buffer.
CMDATALEN=symbol
CMDATALEN=(r2-r12)
(Optional) - Specifies the length of the command response data buffer.

CMDHDR=symbol
CMDHDR=(r2-r12)
(Optional) - Specifies the command response header buffer.

CMDHDRLEN=symbol
CMDHDRLEN=(r2-r12)
(Optional) - Specifies the length of the command response header buffer.

CMDLEN=symbol
CMDLEN=(r2-r12)
(Optional) - Specifies the length of the command input buffer.

CMDTOKEN=symbol
CMDTOKEN=(r2-r12)
(Required) - Specifies a 32-byte field to contain the command token. This token uniquely identifies the command instance that the client has processed. The command token is passed to the client on an OM command directive. The address of the token is passed to the client in the ODIR_CMDTKPTR field in the OM command directive parameter list.

MSGDATA=symbol
MSGDATA=(r2-r12)
(Optional) - Specifies the command response message buffer.

MSGDATALEN=symbol
MSGDATALEN=(r2-r12)
(Optional) - Specifies the length of the command response message buffer.

PARM=symbol
PARM=(r2-r12)
(Required) - Four-byte input parameter that specifies the address of the storage used by the request to pass the parameters to SCI. The length of the parameter list must be equal to the parameter list length EQU value defined by ORSP_PARMLN.

OMNAME=symbol
OMNAME=(r2-r12)
(Required) - Specifies the 8-byte OM name to which to send the command registration request.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. Possible return codes are described in the following table.

The return code can be from OM (CSLOMRSP) or SCI (CSLSCMSG or CSLSCRQS). If ECB is specified, the RETCODE is not valid until the ECB is posted. The value of the high-order byte in the return code identifies whether SCI (X'01') or OM (X'02') provided the return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

RQSTRC=symbol
RQSTRC=(r2-r12)
(Required) - Specifies a 4-byte field to contain the reason code to be passed to the originator of the command. This reason code is defined by the command
processing client and indicates the result of the command. Non-zero reason codes are passed back to the client in the <cmderr> section of the command response.

**RQSTRSN**=symbol
**RQSTRSN**(r2-r12)
(Required) - Specifies a 4-byte field to contain the reason code to be passed to the originator of the command. This reason code is defined by the command processor client and indicates the result of the command. Non-zero reason codes are passed back to the client in the <cmderr> section of the command response.

**RSNCODE**=symbol
**RSNCODE**(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. OM reason codes are defined in the CSLORR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**RSNTEXT**=symbol
**RSNTEXT**(r2-r12)
(Optional) - Specifies a register that must contain the address of the reason text buffer; if specified as a symbol it must be the label of the reason text buffer. The buffer consists of a two-byte length field followed by the reason text. This token allows an OM client to pass a text description of the reason code in a command response.

**RSNTEXTLEN**=symbol
**RSNTEXTLEN**(r2-r12)
(Optional) - Specifies a register that must contain the address of the reason text buffer; if specified as a symbol it must be the label of the reason text buffer. The buffer consists of a two-byte length field followed by the reason text. This token allows an OM client to pass a text description of the reason code in a command response.

**SCITOKEN**=symbol
**SCITOKEN**(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

### CSLOMRSP return and reason codes

The following table lists the return and reason codes that can be returned on a CSLOMRSP macro request. Also included is the meaning of the reason code (that is, what possibly caused it).

**Table 48. CLSOMRSP return and reason codes**

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>

CSLOMSUB: Subscribe to unsolicited messages

With the CSLOMSUB request, single point of control (SPOC) clients can subscribe to OM in order to receive unsolicited output messages from a command processing client, such as IMS.

A message is defined as unsolicited when it is not generated as a response to an input message. For example, system informational messages are unsolicited messages. In an IMS Version 13 IMSplex environment, a command response is considered an unsolicited message if it is returned to a SPOC from which the command did not originate.

All unsolicited output messages are routed to the OM's Output exit routine, which can modify the output. SPOCs can subscribe to the OM using the CSLOMSUB request to have the unsolicited output messages, modified or not, routed to them. To identify unsolicited output messages that should not be directed to OM, you can edit a table that includes messages from OM, RM, SCI, CQS, and the IMS control region that should be ignored.

You must specify an SCI Input exit routine on the SCI registration request (CSLSCREG) to receive unsolicited output messages.

To understand if OM has terminated, specify an SCI Notify exit routine on the SCI registration request, specifying either the RETNAME or RETTOKEN parameter. The SCI Notify exit is called whenever there is a change in status of any member of the IMSplex. Save the RETNAME or RETTOKEN value from the SCI registration and use it to look for a match that indicates that the OM has terminated. The SPOC client can then subscribe to another OM.

This request is supported in Assembler and PLX.

CSLOMSUB syntax

CSLOMSUB FUNC-DSECT syntax

Use the DSECT function of the CSLOMSUB request to include equate (EQU) statements in your logic for the CSLOMSUB parameter list length and return and reason codes.

CSLOMSUB request syntax

With this syntax, SPOC clients can subscribe to OM to receive unsolicited output messages.
CSLOMSUB request parameters

**PARM=parm**

*PARM=(r1-r12)*

Specifies the CSLOMSUB parameter list. The length of the parameter list must be equal to the parameter list length equate (EQU) value that is defined by OSUB_PARM.

**MBRLIST=memberlist**

*MBRLIST=(r1-r12)*

Specifies a member list that identifies the command processing clients (such as IMS control regions) in the IMSplex from which to receive unsolicited output messages. Do not specify the MBRLIST= parameter if you specify the TYPELIST parameter. If you do not specify either the TYPELIST or MBRLIST parameter, the default member list is all the command processing clients in the IMSplex.

Use commas to separate the client names.

**MBRLISTLEN=memberlistlen**

*MBRLISTLEN=(r1-r12)*

Specifies the length of the member list that is specified on the MBRLIST parameter.

**TYPELIST=typelist**

*TYPELIST=(r1-r12)*

Specifies a type list that identifies the valid IMSplex member types from which to receive unsolicited output messages. Do not specify the TYPELIST parameter if you specify the MBRLIST parameter. For valid IMSplex member types, see the TYPE= parameter description in "CSLSCREG: registration request" on page 240. If you do not specify either TYPELIST or MBRLIST parameter, the default list is all command processing clients in the IMSplex.

Use commas to separate the client names.

**TYPELISTLEN=typelistlen**

*TYPELISTLEN=(r1-r12)*

Specifies the length of the type list that is specified by the TYPELIST= parameter.

**RETCODE=returncode**

**RSNCODE=reasoncode**

**SCITOKEN=scitoken**

**RETNAME=omname**

*RETNAME=(r1-r12)*

Specifies an 8-byte output field to receive the name of the OM to which the subscription request is sent.

**RETTOKEN=omscitoken**
RETTOKEN=(r1-r12)
    Specifies a 16-byte output field to receive the OM SCI token that is returned to
    the caller. This is the SCI token for the target OM address space to which SCI
    sent the request.

RETCODE=returncode
RETCODE=(r1-r12)
    Specifies a 4-byte field to receive the output return code. OM return codes are
    defined in the CSLORR. SCI return codes are defined in CSLSRR.

OM or SCI provides the return code. The value of the high-order byte in the
return code identifies whether SCI (X'01') or OM (X'02') provided the return
code.

RSNCODE=reasoncode
RSNCODE=(r1-r12)
    Specifies a 4-byte field to receive the output reason code. OM return codes are
    defined in the CSLORR. SCI return codes are defined in the CSLSRR.

SCITOKEN=scitoken
SCITOKEN=(r1-r12)
    Specifies a 16-byte field that contains the SCI token, which uniquely identifies
    this connection to SCI. The SCI token is returned by a successful CSLSCREG
    FUNC=REGISTER request.

CSLOMSUB return and reason codes

The return and reason codes shown in the following table can be returned on a
CSLOMSUB request.

Table 49. CSLOMSUB request return and reason codes

<table>

</tbody>
</table>

Usage notes

If a SPOC subscribes to OM to receive unsolicited output messages, the default is
to send all messages to that subscriber. You can prevent IMS, CQS, and CSL
messages from being sent as unsolicited output by populating and maintaining a
table of messages by using the following macros.

Macro       Description

CSLZUMT      Use this macro to populate table CSLZUMTU with CSL messages that
             should not be routed to subscribers as unsolicited messages.

CQSUOMT     Use this macro to populate table CQSUOMTU with CQS messages that
             should not be routed to subscribers as unsolicited messages.

DFSUOMT     Use this macro to populate table DFSUOMTU with IMS messages that
             should not be routed to subscribers as unsolicited messages.
Samples of the CQSUOMTU, CSLZUMTU, and DFSUOMTU tables are provided in the IMS sample library.

An example of the CSLZUMT macro is shown in the following example. In this example, messages CSL2020I and CSL2021E are added to the CSLZUMTU table, and are therefore prevented from being sent as unsolicited output messages to subscribed clients.

```plaintext
CSLZUMT MESSAGE=CSL2020I
CSLZUMT MESSAGE=CSL2021E
```

You can also specify MESSAGE=SUPPRESS in the CQSUOMTU, CSLZUMTU, and DFSUOMTU tables. For example, if you code the following in message table DFSUOMTU, messages DFSxxxxx and DFSyyyyy will be sent to OM, message DFSzzzzz will not be sent to OM, and any other messages will not be sent to OM because of the MESSAGE=SUPPRESS statement:

```plaintext
DFSUOMT MESSAGE=DFSxxxxx,SEND=YES
DFSUOMT MESSAGE=DFSyyyyy,SEND=YES
DFSUOMT MESSAGE=DFSzzzzz,SEND=NO
DFSUOMT MESSAGE=SUPPRESS
```

Another way to control which unsolicited output messages are sent to OM from IMS is to use the new UOM=MTO | NONE | ALL parameter for the DFSDFxxx and DFSCGxxx IMS PROCLIB members.

- With UOM=MTO specified, messages that are destined for the MTO only or system console (or both) only will be sent to OM. Messages being sent to other destinations, such as end user terminals, will not be sent to OM.
- With UOM=NONE specified, no messages will be sent to OM.
- With UOM=ALL specified, all messages will be sent to OM.

### CSLOMUSB: Unsubscribe to unsolicited messages

With the CSLOMUSB request, SPOC clients can unsubscribe to OM and stop receiving unsolicited output messages from a command processing client, such as IMS.

This request is supported in Assembler and PLX.

**CSLOMUSB syntax**

**CSLOMUSB FUNC-DSECT syntax**

Use the DSECT function of the CSLOMUSB request to include equate (EQU) statements in your logic for the CSLOMUSB parameter list length and return and reason codes.

```plaintext
CSLOMUSB FUNC=DSECT
```

**CSLOMUSB request syntax**

With this syntax, SPOC clients can unsubscribe from OM to stop receiving unsolicited output messages.

```plaintext
CSLOMUSB FUNC=UNSUBSCRIBE PARM=parm RETCODE=returncode
```
CSLOMUSB parameters

**PARM**=parm

Specifies the CSLOMUSB parameter list. The length of the parameter list must be equal to the parameter list length equate (EQU) value that is defined by OUSB_PARMLN.

**RETCODE**=returncode

Specifies a 4-byte field to receive the output return code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

OM or SCI provides the return code. The value of the high-order byte in the return code identifies whether SCI (X'01') or OM (X'02') provided the return code.

**RSNCODE**=reasoncode

Specifies a 4-byte field to receive the output reason code. OM return codes are defined in the CSLORR. SCI return codes are defined in CSLSRR.

**SCITOKEN**=scitoken

Specifies a 16-byte field that contains the SCI token, which uniquely identifies this connection to SCI. The SCI token is returned by a successful CSLSCREG FUNC=REGISTER request.

CSLOMUSB return and reason code

The return and reason codes shown in the following table can be returned on a CSLOMUSB request:

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
</tbody>
</table>

CSL OM directives

An OM directive is a function that OM defines that can be sent as a message to OM clients to inform the OM clients of work to be processed. Any command processing client that has registered commands to OM can be selected to perform an OM directive.

OM directives are always issued in message protocol (PROTOCOL=MSG), that is, asynchronously; OM therefore expects no response from the OM client, and it continues processing without waiting for a response. The OM client is responsible for determining whether or not to take any action in response to the directive.

When a client issues PROTOCOL=MSG, SCI sends the XML output from OM to the client's SCI Input exit. The SCI Input exit routine's INXP_MBRPPLPTR field points to the CSLOMDIR parameter list.
When a client issues CSLOMI PROTOCOL=RQST, the XML output stream from OM is sent directly to the client in the OUTPUT= parameter.

The SCI Input exit routine is responsible for notifying the client of the directive. The client should code their SCI Input exit routine to support OM directives. The client is responsible for determining where the function and function code are to be defined. After the client is finished using the CSLOMDIR parameter list, it must release the storage by issuing CSLSCBFR.

OM directives are defined in the CSLOMDIR macro, which includes:
- Command directive (ODIR_CMDD)
- CSLOMI response directive (ODIR_OMIRESPD)
- Command response directive (ODIR_CMDRESPD)
- Query response directive (ODIR_QRYRESPD)

The directives and their parameters are described in this topic.

**CSL OM command directive**

The OM command directive, ODIR_CMDD, is sent to a command processing client when a command is available for processing.

The parameters for the OM command directive follow. They are passed to the SCI Input Exit:

- ODIR_COMMAND Identifies the start of the command directive.
- ODIR_CMDDKLEN=length Contains the length of the OM command token. It is used only by OM to identify the command instance.
- ODIR_CMDDKPTR=address Contains the address of the OM command token.
- ODIR_INPUTLEN=length Contains the length of the command input string that you enter.
- ODIR_INPUTPATOR=address Contains the address of the command input string.
- ODIR_VERBLEN=length Contains the length of the command verb in normalized form.
- ODIR_VERBPTR=address Contains the address of the command verb.
- ODIR_KWDLEN=length Contains the length of the command keyword.
- ODIR_KWDPTR=address Contains the address of the command keyword.
- ODIR_PARSELEN=length Contains the length of the parsed command block.
- ODIRPARSEPTR=address Contains the address of the parsed command block.
- ODIR_CUIDLEN=length Contains the length of the user ID that originated the command.
ODIR_CUIDPTR=address
Contains the address of the user ID that originated the command.

ODIR_CNAMELEN=length
Contains the length of the name of the client that originated the command
(that is, the name that was registered to SCI).

ODIR_CNAMEPTR=address
Contains the address of the name of the client that originated the command
(that is, the name that was registered to SCI).

ODIR_CTYPE=client type
Contains the type of client that originated the command. This is the value from
the TYPE= parameter as defined to SCI. This parameter is passed by value; the
length field is always zero.

ODIR_CSTYPLEN=length
Contains the subtype of the client that originated the command. This is the
value from the SUBTYPE= parameter as defined to SCI.

ODIR_CSTYPPTR=length
Contains the address of the subtype of the client that originated the command.

ODIR_CFLAGS=flags
Contains the OM command processing flags. These parameters are passed by
value; the length field is always zero.

ODIR_CRQTKLEN=length
Contains the length of the user request token; this parameter is used only by
the program that originated the command to identify the command instance.

ODIR_CRQTKPTR=address
Contains the address of the user request token; this parameter is used only by
the program that originated the command to identify the command instance.

ODIR_TIMEOUT=timeoutvalue
Contains the command timeout value as specified on the command. This
parameter is passed by value; the length field is always zero.

ODIR_CMDLN
The command directive length EQU.

CSL OM response directives

There are three response directives in CSLOMDIR:

- CSLOMI response (ODIR_OMIRESPD)
The CSLOMI response directive returns a response to a client regarding a
CSLOMI call. The response is sent when an error occurs and it is unclear if the
response is for a CSLOMI CMD or CSLOMI QUERY call.

- Command response (ODIR_CMDRESPD)
The command response directive returns a command response to a client that
results from a CSLOMI CMD or CSLOMCM call.

- Query response (ODIR_QRYRESPD)
The query response directive returns a query response to a client that results
from a CSLOMI QUERY or CSLOMQUERY call.

The parameters for the OM response directives are identical.

ODIR_CQRESP
Identifies the start of the command or query response.
**ODIR_CQSPRC** = returncode  
Contains the return code of the command or query response.

**ODIR_CQSPRSN** = reasoncode  
Contains the reason code of the command or query response.

**ODIR_CQXMLLEN** = length  
Contains the length of the XML output being returned.

**ODIR_CQXMLPTR** = address  
Contains the address of the XML output being returned.

**ODIR_CQRT1LEN** = length  
Contains the length of request token 1 (RQSTTKN1).

**ODIR_CQRT1PTR** = address  
Contains the address of request token 1 (RQSTTKN1).

**ODIR_CQRT2LEN** = length  
Contains the length of request token 2 (RQSTTKN2).

**ODIR_CQRT2PTR** = address  
Contains the address of request token 2 (RQSTTKN2).

**ODIR_CQRTLEN**  
The response directive length EQU.

**CSL UOM directive**

The OM unsolicited output message (UOM) directive, ODIR_UOM, is sent to any OM client that subscribes to OM. You define this directive in CSLOMDIR.

The parameters for the UOM directive are passed to the OM client's SCI Input exit routine.

**ODIR_UOM**  
Identifies the start of the UOM directive parameters.

**ODIR_UOMXMLLEN** = length  
Contains the length of the XML output that is sent.

**ODIR_UOMXMLPTR** = address  
Contains the address of the unsolicited output message, wrapped in XML tags.

**ODIR_UOMLN**  
The UOM directive length equate (EQU) value.

**ODIR_UOMCR**  
Identifies the start of the command response UOM directive parameters, which inform the subscribing client that this is a command response sent as an unsolicited message.

**ODIR_UOMXMLLEN** = length  
Contains the length of the XML output that is sent.

**ODIR_UOMXMLPTR** = address  
Contains the address of the unsolicited output message, wrapped in XML tags.

**ODIR_UOMLN**  
The UOM directive length equate (EQU) value.

BPE-based CSL SCI user exit routines (Exit Routines)
Chapter 7. Writing a CSL RM client

The topics in this section describe the client requests and directives for writing an RM client.

Sequence of RM client requests

If you want to use RM to manage global resources in an IMSplex for your own product or service, you have to write one or more RM clients. An RM client uses RM requests issued in a particular sequence to communicate with RM.

To write an RM client, you can use the set of client requests provided by RM. These requests allow a client to access RM or resources on a resource structure, or to coordinate an IMSplex-wide process. One example of an RM client is IMS. You can write an RM client in assembler language.

An RM client uses RM requests to make use of RM services and resources. A client issues SCI and RM requests to request RM services. Some of the requests must follow a particular sequence. Other requests can be issued multiple times, in any order, based on the processing requirements of the client.

Before an RM client can issue RM requests, it must register:
- To SCI
- To each active RM in the IMSplex, so any RM can process an RM request
- Its own resource types and associated name types to RM

The following table lists the sequence of requests issued by an RM client. The request is listed with its purpose.

Table 51. Sequence of requests for an RM client

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSLSCREG</td>
<td>Registers to SCI, which enables the client to send RM requests to RM through SCI.</td>
</tr>
<tr>
<td>CSLSCRDY</td>
<td>Readies the RM client to SCI, which routes messages to the client by client type.</td>
</tr>
<tr>
<td>CSLRMREG</td>
<td>Registers client to RM to enable communication with RM. The client should register to each active RM in the IMSplex, so any RM can process an RM request. The client can also register its own resource types and associated name types to RM.</td>
</tr>
<tr>
<td>CSLRMxxx</td>
<td>Issues RM resource requests such as CSLRMupd, CSLRMdel, CSLRmqry to manipulate resources on a resource structure.</td>
</tr>
<tr>
<td>CSLRMPxx</td>
<td>Issues RM process requests such as CSLRmpri, CSLRmprs, CSLRmprr, and CSLRmprt to participate in an IMSplex-wide process.</td>
</tr>
<tr>
<td>CSLSCBFR</td>
<td>Releases the output buffer returned by the request, if any.</td>
</tr>
<tr>
<td>CSLRMDRG</td>
<td>Deregisters client from RM to end communications with RM.</td>
</tr>
<tr>
<td>CSLSCDRG</td>
<td>Deregisters from SCI.</td>
</tr>
</tbody>
</table>
The following table lists the sequence of requests issued by an RM client that is participating in IMSplex-wide processes. The request is listed with its purpose.

Table 52. Sequence of requests for an RM client participating in IMSplex-wide process

“CSLRMREG: register clients” on page 208

Issue CSL RM requests to manage global resources

Before a client can access or change global resource information, it must register to SCI using the CSLSCREG request. After the client registers to SCI, it must register to RM using the CSLRMREG request. The client must issue an SCI registration request for every IMSplex with which it intends to communicate.

Before a client can access or change global resource information, it must register to SCI using the CSLSCREG request.

After the client registers to SCI, it must register to RM using the CSLRMREG request.

When the client is ready to terminate, it must deregister from RM using the CSLRMDRG request and then deregister from SCI using the CSLSCDRG request.

“CSLRMUPD: update resources” on page 212

Issue CSL RM requests to coordinate IMSplex-wide processes

You can use RM-supplied requests to coordinate IMSplex-wide processes. All clients that are to participate in the process register to RM using the RM client registration request (CSLRMREG). After the clients are registered, several different requests can be utilized to coordinate processes.

One client initiates the process using the RM process initiate request (CSLRMPRI). The same or a different client initiates a step using RM process step request (CSLRMPRS). The initiating client is called the master of the step. One RM
processes the request and sends RM directives to the other clients to perform the process step. All the other clients process the step, build output, and then respond to the step using the RM process respond request (CSLRMPRR). RM consolidates the responses from all the clients into one output, and then returns the output to the master of the process step. If there are more steps in the process, a client initiates a step, and the clients perform processing and respond. Any client terminates the process using the RM process terminate request (CSLRMPRT). Clients can deregister using the RM client deregistration request (CSLRMDRG) if required.

Some failures can cause RM to lose all knowledge of an IMSplex-wide process. These include resource structure failure (and its duplex, if applicable) and failure of all RMs. If this type of failure occurs, each RM client should clean up knowledge of the process locally, and a master RM should terminate the process. The first RM client to detect a problem can initiate a clean up process step by issuing the CSLRMPRS request with the force option to enable RM to force the process step, regardless of the error. The clients participating in the process step clean up the process locally. The master of this process step then terminates the process with the CSLRMPRT request.

The CSLRMPRI, CSLRMPRR, CSLRMPRS, and CSLRMPRT requests can be used to coordinate IMSplex-wide processes.

“CSLRMPRT: process terminate” on page 201

CSLRMDEL: delete resources

You can issue the CSLRMDEL request to delete one or more uniquely named resources, or all resources by owner for a specific resource type on a resource structure.

This request is supported in assembler language.

CSLRMDEL syntax

CSLRMDEL DSECT syntax

Use the DSECT function of a CSLRMDEL request to include the following resources in your program:

- Equate (EQU) statement for the CSLRMDEL parameter list length
- The CSLRMDEL return codes, reason codes, and completion codes
- The CSLRDELL DSECT to map the input delete list
- The CSLRDELO DSECT to map the delete output

CSLRMDEL DELETE syntax

Use the DELETE function of a CSLRMDEL request to delete one or more uniquely named resources on a resource structure.
CSLRMDEL parameters

**ECB**=symbol

(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRMDEL before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).

**LIST**=symbol

(Required) - Specifies the delete resource list built by the caller. Each list entry is a separate delete request. The list length can vary, depending on the number of list entries.

CSLRDELL maps the delete resource list entry. The list contains a header and one or more list entries. The list entries must reside in contiguous storage. Each delete list entry contains information about what to delete.

For delete by resource name, to delete a uniquely named resource:

• Resource name - the client-defined name of the resource.

• Resource type - a client-defined physical grouping of resources on the resource structure. Valid values are 1-255.

• Version - resource version, which is the number of times the resource has been updated.

For delete by owner, to delete all resources owned by a particular owner for a resource type, regardless of the resource version:

• Resource type - a client-defined physical grouping of the resources on the resource structure. Valid values are 1-255.

• Owner - resource owner.

**LISTLEN**=symbol

(Required) - Specifies the 4-byte delete resource list length.

**OUTLEN**=symbol

(Required) - Specifies a 4-byte field to receive the length of the output returned by the CSLRMDEL request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.
OUTPUT=output
OUTPUT=(r2-r12)

(Required) - Specifies a 4-byte field to receive the address of the variable length output returned by the CSLRMDEL request. The output contains a header and one or more delete entries for resource deletes that were attempted. The output length is returned in the OUTLEN= field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The CSLRDELO macro maps the output that is returned. The output contains a header and one or more list entries.

The output header contains the following parameters:
- Eyecatcher
- Output length
- CSLRDELO version
- CSLRDELO header length (offset to start of entries)
- CSLRDELO entry length
- Resource entry count

Each output entry represents a resource delete that failed. Each entry contains the following parameters:
- Output entry length - the list entry length
- Name type - a client-defined value associated with a resource type that ensures uniqueness of client-defined resource names within a name type. Valid values are 1-255.
- Resource name
- Resource type
- Delete type
- Version - resource version of an existing resource if the delete request failed because of a version mismatch.
- Owner - resource owner of an existing resource if the delete failed because of a version mismatch and the option to read the owner was set.
- Completion code for the delete request. Completion codes are mapped by CSLRRR.

Possible completion codes are:

X'00000008'
  Invalid resource type.

X'00000010'
  Version mismatch. The version specified on input does not match the resource's version, so delete fails.

X'00000018'
  Resource type is not registered. The resource type must be registered by using a CSLRMREG request.

X'00000024'
  Resource structure is unavailable.

X'00000038'
  Delete failed because of CQS internal error.

X'0000003C'
  Delete failed because RM incorrectly built the CQSDEL list entry.
The output buffer is not preallocated by the caller. After being returned from the request, this word contains the address of a buffer containing the delete output. It is the caller's responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is through with the storage. The length of the output is returned in the OUTLEN= field.

**PARM=**

**PARM=(r2-r12)**

(Required) - specifies the CSLRMDEL parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RDEL_PARMLEN.

**RETCODE=**

**RETCODE=(r2-r12)**

(Required) - specifies a 4-byte field to receive the return code on output. RM return codes are defined in CSLRRR. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

**RETNAME=**

**RETNAME=(r2-r12)**

(Optional) - Specifies an 8-byte field to receive the RM name returned to the caller. This is the CSL member name of the target RM address space to which SCI sent the request.

**RETTOKEN=**

**RETTOKEN=(r2-r12)**

(Optional) - Specifies a 16-byte field to receive RM's SCI token returned to the caller. This is the SCI token for the target RM address space to which SCI sent the request.

**RSNCODE=**

**RSNCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRRR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=**

**SCITOKEN=(r2-r12)**

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

### CSLRMDEL return and reason codes

The following table lists the return and reason codes that can be returned on a CSLRMDEL request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'03000008'</td>
<td>X'000002000'</td>
<td>The client is not registered.</td>

CSLRMDRG: deregister clients

The deregister request is issued by a client when the client no longer wants to process resource requests or IMSplex-wide process requests from RM. The deregister request removes client information from RM and stops RM from sending new resource requests to the client. Some information about the client is retained that can affect IMSplex-wide processes.

This request is issued by resource processing clients such as the IMS control region.

This request is supported in assembler.

**CSLRMDRG syntax**

**CSLRMDRG DSECT syntax**

**CSLRMDRG deregister syntax**

Use the DEREGISTER function of a CSLRMDRG request to deregister from RM.

```
CSLRMDRG FUNC=DEREGISTER PARM=parm
OPTWORD1=deregisteroptions
RETCODE=returncode RSNCODE=reasoncode SCITOKEN=scitoken
```

**CSLRMDRG parameters**

OPTWORD1=symbol

OPTWORD1=(r2-r12)

(Optional) - Specifies a 4-byte field containing deregistration options.

CSLRMDRG FUNC=DSECT generates the equates for deregistration options.

X'80000000'

Remove client from IMSplex. Delete all knowledge of the client.

PARM=symbol

PARM=(r2-r12)

(Required) - Specifies the CSLRMDRG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RDRG_PARMLEN.

RETCODE=symbol

RETCODE=(r2-r12)

(Required) - Specifies a 4-byte field to receive the return code on output. RM return codes are defined in CSLRRR. RM does not return a response to the CSLRMDRG request.

RSNCODE=symbol

RSNCODE=(r2-r12)

(Required) - Specifies a 4-byte field to receive the reason code on output. SCI reason codes are defined in CSLSRR. RM does not return a response to the CSLRMDRG request.

SCITOKEN=symbol

SCITOKEN=(r2-r12)

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.
Related concepts:
“Issue CSL RM requests to manage global resources” on page 184

CSLRMPI: process initiate

With the CSLRMPRI request, a client can initiate a process across an IMSplex. RM ensures that only one IMSplex-wide process of a type can be in progress at one time. The process initiation fails if any other IMSplex-wide process of the type is in progress.

This request is supported in assembler language.

CSLRMPI syntax

CSLRMPI DSECT syntax

Use the DSECT function of a CSLRMPRI request to include equate (EQU) statements in your program for the length of the CSLRMPRI parameter list.

CSLRMPI INITIATE syntax

Use the INITIATE function of a CSLRMPRI request to initiate an IMSplex-wide process.

CSLRMPI parameters

ECB=symbol
ECB=(r2-r12)
(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRMPRI before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).

PARM=symbol
PARM=(r2-r12)
(Required) - Specifies the CSLRMPRI parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RPRI_PARM LN.

PRCNAME=symbol
PRCNAME=(r2-r12)
(Required) - Specifies an 8-byte field containing the process name. The process
name is client defined and has no meaning to RM. RM uses the process name and the process type to ensure that only one instance of a process of a particular process type is in progress at one time.

PRCTOKEN=symbol
PRCTOKEN=(r2-r12)
(Required) - Specifies a 16-byte field to receive the process token returned to the caller. The process token uniquely identifies the process instance. The process token returned is zero, if the IMSplex is defined with a resource structure. The process token is non-zero, if the IMSplex is not defined with a resource structure. The process token must be specified as input on any subsequent CSLMPRS, CSLMRPR, or CSLMPRT request.

PRCTYPE=symbol
PRCTYPE=(r2-r12)
(Required) - Specifies a 1-byte client-defined process type. Only one process of a particular type can be in progress at any one time. The process type can be 1 through 255.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. RM return codes are defined in CSLRRR. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

RETNAMESymbol
RETNAMESymbol=(r2-r12)
(Optional) - Specifies an 8-byte field to receive the RM name returned to the caller. This is the CSL member name of the target RM address space to which SCI sent the request.

RETTOKEN=symbol
RETTOKEN=(r2-r12)
(Optional) - Specifies a 16-byte field to receive RM's SCI token returned to the caller. This is the SCI token for the target RM address space to which SCI sent the request.

RSNCODE=symbol
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRRR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

SCITOKEN=symbol
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

UOWTOKEN=symbol
UOWTOKEN=(r2-r12)
(Required) - specifies a 16-byte field containing the unit of work token. The UOW token uniquely identifies an instance of this process and ties all of the process steps together. The UOW token must be specified on the RM process step request, CSLMPRS. The UOW token is client-defined and has no meaning to RM.
CSLRMPRI return and reason codes

The following table lists the return and reason codes that can be returned on a CSLRMPRI request. Also included is the meaning of a reason code (that is, what possibly caused it).

Table 54. CSLRMPRI return and reason codes

CSLRMPRR: process respond

By issuing the CSLRMPRR request, a client can respond to a step in an IMSplex-wide process.

This request is supported in assembler language.

CSLRMPRR syntax

CSLRMPRR DSECT syntax
Use the DSECT function of a CSLRMPRR request to include equate (EQU) statements in your program for the length of the CSLRMPRR parameter list.

```
CSLRMPRR FUNC=DSECT
```

**CSLRMPRR RESPOND syntax**

Use the RESPOND function of a CSLRMPRR request to respond to a step in an IMSplex-wide process.

```
CSLRMPRR FUNC=RESPOND PARM=parm PRCTOKEN=processtoken
```

```
OUTPUT=output OUTLEN=outputlength
```

```
RETCODE=returncode RSNCODE=reasoncode RQSTRC=processreturncode
```

```
RQSTRSN=processreasoncode SCITOKEN=scitoken
```

**CSLRMPRR parameters**

**OUTLEN=symbol**

**OUTLEN=(r2-r12)**

(Required) - Specifies a 4-byte input field that contains the length of the process step output buffer. OUTLEN= contains the length of the output pointed to by the OUTPUT= parameter.

**OUTPUT=output**

**OUTPUT=(r2-r12)**

(Required) - Specifies a 4-byte field that contains the address of the output buffer built by the caller. The output is client-defined and contains the results from this client’s processing of the step. The output length is returned in the OUTLEN= field.

**PARM=symbol**

**PARM=(r2-r12)**

(Required) - Specifies the CSLRMPRR parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RPRR_PARMLN.

**PRCTOKEN=symbol**

**PRCTOKEN=(r2-r12)**

(Required) - Specifies a 16-byte field that contains the process token that uniquely identifies the process. This token was returned on a successful CSLRMPRI FUNC=INITIATE request.

If the IMSplex is defined with a resource structure, the process token is zero.

**RETCODE=symbol**

**RETCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSR. RM does not return a response to CSLRMPRR.

**RMNAME=symbol**

**RMNAME=(r2-r12)**

(Required) - Specifies an 8-byte field containing the RM name to which to send the process step response. This is the RM that originated the process step.
RQSTRC=\textit{symbol}
RQSTRC=\textit{(r2-r12)}

\textit{(Required)} - Specifies a 4-byte field that contains the return code to be passed to the originator of the process step on output. The return code is defined by the process step originating client and indicates the result of the process step.

RQSTRSN=\textit{symbol}
RQSTRSN=\textit{(r2-r12)}

\textit{(Required)} - Specifies a 4-byte field that contains the reason code to be passed to the originator of the process step on output. The reason code is defined by the process step originating client and indicates the result of the process step.

RSNCODE=\textit{symbol}
RSNCODE=\textit{(r2-r12)}

\textit{(Required)} - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRRR. RM does not return a response to CSLRMPRR.

SCITOKEN=\textit{symbol}
SCITOKEN=\textit{(r2-r12)}

\textit{(Required)} - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG \texttt{FUNC=REGISTER} request.

\textbf{CSLRMPRR return and reason codes}

CSLRMPRR is sent to the target client address space using the SCI message protocol; RM does not return codes to CSLRMPRR. All return and reason codes that are applicable to the CSLSCMSG request can be returned on a CSLRMPRR request.

\textbf{Related concepts:}

\begin{itemize}
  \item \href{#issue-csl-rm-requests-to-manage-global-resources}{“Issue CSL RM requests to manage global resources” on page 184}

\end{itemize}

\textbf{CSLRMPRS: process step}

By issuing the CSLRMPRS request, a client can perform a step in an IMSplex-wide process that can consist of zero, one, or more steps.

This request is supported in assembler language.

\textbf{CSLRMPRS syntax}

\textbf{CSLRMPRS DSECT syntax}

Use the DSECT function of a CSLRMPRS request to include equate (EQU) statements in your program for the length of the CSLRMPRS parameter list and the process step request options.

\begin{itemize}
  \item \texttt{CSLRMPRS—FUNC=DSECT}
\end{itemize}

\textbf{CSLRMPRS PROCESS syntax}

Use the PROCESS function of a CSLRMPRS request to perform a step in an IMSplex-wide process.
CSLRMPRS parameters

CDATA=\text{symbol}

CDATA=(r2-r12)

(Optional) - Specifies a variable length area that contains client data to send to clients participating in the IMSplex-wide process step. The client data has meaning to clients, not to RM.

CDATALEN=\text{symbol}

CDATALEN=(r2-r12)

(Optional) - Specifies a 4-byte input field that contains the client data length. If this parameter is specified, CDATA= must also be specified.

ECB=\text{symbol}

ECB=(r2-r12)

(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRM PRS before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).

LIST=\text{symbol}

LIST=(r2-r12)

(Required) - Specifies the variable length input list that contains the list of clients to which to send the process step.

The process step list contains a list header and one or more list entries. The list header contains the list header length, the parameter list version, the list entry length, the list entry count, and a user data area. The list header user data area is passed back to the requestor in the list header of the process step output. Each list entry contains the client name and an optional user data area. The
user data area is passed back to the requestor in a list entry in the process step output. The list entries must reside in contiguous storage.

The CSLRPRSL macro maps the process step list.

**LISTLEN=**

**LISTLEN=(r2-r12)**

(Required) - Specifies a 4-byte input field that contains the process step list length.

**OPTWORD1=**

**OPTWORD1=(r2-r12)**

(Optional) - Specifies a 4-byte field containing the process step options.

CSLRMPRS FUNC=DSECT maps the process step options.

X'80000000'

Force process step after error. Take over a process step in progress, if a process step is already in progress for an IMSples member that is not active. Initiate a process and perform a process step if no process is known to be in progress due to an error such as resource structure failure.

**OUTLEN=**

**OUTLEN=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the length of the output buffer returned by the CSLRMPRS request. After being returned by request, this word contains the length of the buffer pointed to by the OUTPUT= parameter. If no output is built, the output buffer length is zero. This can occur if an error is detected before any output can be built.

It is the caller's responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is through with the storage.

**OUTPUT=**

**OUTPUT=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the address of the variable length output buffer returned by the CSLRMPRS request. The output buffer contains the client-defined data from each participating client and indicates the results of the process step. The output buffer length is returned in the OUTLEN= field.

If no output is built, the output buffer address is zero. This can occur if an error is detected before any output can be built.

The CSLRPRSO macro maps the output buffer that is returned. The output buffer header contains an eyecatcher, the output buffer length, the CSLRPRSO version, the header length (offset to start of the process list entries), the list entry minimum size, the process list entry count, a user data area, and the CSLRPRSO create time stamp. The user data area contains the user data passed in the input process step list header.

Each output buffer entry represents the results from a client that participated in a process step. Each entry contains the following:

- Entry length
- Client name
- User data - the user data passed in the input process step list
- Process step response length
- Process step response
- Completion code (CSLRRR) - possible completion codes are:
Client processes step successfully.

Client did not respond before the process step timed out.

The client was not sent the process step request because the client is not registered to RM.

This buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing information from the IMSplex members participating in the process. It is the caller’s responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is through with the storage.

**PARM=**

**PARM=(r2-r12)**

(Required) - Specifies the CSLRMPRS parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RPRS_PARMLN.

**PRCNAME=**

**PRCNAME=(r2-r12)**

(Required) - Specifies an 8-byte field containing the process name. The process name is client defined and has no meaning to RM. RM uses the process name and type to ensure that only one instance of a process, with a particular process type, is in progress at one time.

**PRCTOKEN=**

**PRCTOKEN=(r2-r12)**

(Required) - Specifies a 16-byte field that contains the process token that uniquely identifies the process. This token was returned on a successful CSLRMPRI FUNC=INITIATE request.

If the IMSplex is defined with a resource structure, the process token is zero.

**PRCTYPE=**

**PRCTYPE=(r2-r12)**

(Required) - Specifies a 1-byte client-defined process type. Only one process of a particular type can be in progress at any one time. The process type can be 1 through 255.

**RETCODE=**

**RETCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSRR. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

**RETNAME=**

**RETNAME=(r2-r12)**

(Optional) - Specifies an 8-byte field to receive the RM name returned to the caller. This is the CSL member name of the target RM address space to which SCI sent the request.

**RETNAME=**

**RETNAME=(r2-r12)**

(Optional) - Specifies an 8-byte field to receive the RM name returned to the caller. This is the CSL member name of the target RM address space to which SCI sent the request.
RSNCODE= symbol
RSNCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRERR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

SCITOKEN= symbol
SCITOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

STEPNAME= symbol
STEPNAME=(r2-r12)
(Required) - Specifies a 4-byte field containing the process step name. The process step name is client-defined and has no meaning to RM. Each process step must have a different name.

TIMEOUT= timeoutvalue
TIMEOUT= symbol
TIMEOUT=(r2-r12)
(Optional) - Specifies a 4-byte field containing the process step timeout value in seconds. If the timeout value is reached during the processing of the step, before all of the participants have responded to the process step, RM terminates the process step and returns the available responses. If the specified timeout value is too small, an incomplete response is returned. The TIMEOUT value ensures a response is returned even if a client processing the step is unable to respond.

The default timeout value is 5 minutes (300 seconds). Specify a negative one (-1) value if no timeout is required for the request.

The TIMEOUT value is the shortest possible time value that can cause the process step to time out. RM internally sets a timer to pop every 5 seconds. When the RM timer pops, RM checks to see if any process step timeout value has expired. When the process step timeout value is less than the RM timer value, the actual length of step processing can be longer than the user specified TIMEOUT value.

UOWTOKEN= symbol
UOWTOKEN=(r2-r12)
(Required) - Specifies a 16-byte field containing the unit of work token. The UOW token uniquely identifies an instance of this process and ties all of the process steps together. The UOW token must match the UOW token specified on the CSLRMPRI FUNC=INITIATE request. The UOW token is client-defined and has no meaning to RM.

CSLRMPRS return and reason codes

The following table lists the return and reason codes that can be returned on a CSLRMPRS request. Also included is the meaning of a reason code (that is, what possibly caused it).

CSLRMPRT: process terminate

You can issue the CSLRMPRT request to terminate an IMSplex-wide process. Any client that is participating in the process can issue a CSLRMPRT FUNC=TERMINATE request to terminate the process.

This request is supported in assembler language.

CSLRMPRT syntax

The syntax for the CSLRMPRT request follows.

DSECT syntax

Use the DSECT function of a CSLRMPRT request to include equate (EQU) statements in your program for the length of the CSLRMPRT parameter list.

`►►CSLRMPRT-FUNC=DSECT◄◄`

TERMINATE syntax

Use the TERMINATE function of a CSLRMPRT request to terminate an IMSplex-wide process.

`►►CSLRMPRT-FUNC=TERMINATE[OPTWORD1=processtermoptions]PARM=parm◄◄`
CSLRMPRT parameters

OPTWORD1=symbol
OPTWORD1=(r2-r12)
(Optional) - Specifies a 4-byte field containing the process terminate options. CSLRMPRT FUNC=DSECT maps the process terminate options. OPTWORD1 can have a value of X'80000000'.

PARM=symbol
PARM=(r2-r12)
(Required) - Specifies the CSLRMPRT parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RPR_PARMLEN.

PRCNAME=symbol
PRCNAME=(r2-r12)
(Required) - Specifies an 8-byte field containing the process name. The process name is client defined and has no meaning to RM. RM uses the process name and the process type to ensure that only one instance of a process of a particular process type is in progress at one time.

PRCTOKEN=symbol
PRCTOKEN=(r2-r12)
(Required) - Specifies a 16-byte field that contains the process token that uniquely identifies the process. This token was returned on a successful CSLRMPRI FUNC=INITIATE request.

If the IMSplex is defined with a resource structure, the process token is zero.

PRCTYPE=symbol
PRCTYPE=(r2-r12)
(Required) - Specifies a 1-byte client-defined process type. Only one process of a particular type can be in progress at any one time. The process type can be 1 through 255.

RETCODE=symbol
RETCODE=(r2-r12)
(Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSRR. RM does not return a response to CSLRMPRT.

RETNAMEx=RETNAME
RETNAMEx=(r2-r12)
(Optional) - Specifies an 8-byte field to receive the name of the RM address space to which SCI sent the process terminate request.

RETTOKEN=symbol
RETTOKEN=(r2-r12)
(Optional) - Specifies a 16-byte field to receive the SCI token of the RM address space to which SCI sent the process terminate request.

RSNCODE=SYMBOL
RSNCODE=REASONCODE
RSNCODE=SCITOKEN
RSNCODE=\((r2-r12)\)
(Required) - Specifies a 4-byte field to receive the reason code on output. SCI reason codes are defined in CSLSRR. RM does not return a response to the CSLRMPRT request.

SCITOKEN=\(\text{symbol}\)
SCITOKEN=\((r2-r12)\)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

UOWTOKEN=\(\text{symbol}\)
UOWTOKEN=\((r2-r12)\)
(Required) - Specifies a 16-byte field containing the unit of work token. The UOW token uniquely identifies an instance of this process and ties all of the process steps together. The UOW token must match the UOW token specified on the CSLRMPI FUNC=INITIATE request. The UOW token is client-defined and has no meaning to RM.

**CSLRMPRT return and reason codes**

CSLRMPRT is sent to the target client address space using the SCI message protocol. All return and reason codes that are applicable to the CSLSCMSG request can be returned on a CSLRMPRT request. CSLRMPRT does not issue any additional return and reason codes.

**Related concepts:**
- “Issue CSL RM requests to manage global resources” on page 184
- “Issue CSL RM requests to coordinate IMSplex-wide processes” on page 184

---

**CSLRMQRY: query resources**

You can issue the CSLRMQRY request to query one or more uniquely named resources on a resource structure.

This request is supported in assembler language.

**CSLRMQRY syntax**

**CSLRMQRY DSECT syntax**

Use the DSECT function of a CSLRMQRY request to include the following inputs and outputs in your program:

- Equate (EQU) statements for the length of the CSLRMQRY parameter list
- The CSLRMQRY return codes, reason codes, and completion codes
- The CSLRQRYL DSECT to map the input query list
- The CSLRQRYO DSECT to map the query output

---

**CSLRMQRY QUERY syntax**

Use the QUERY function of a CSLRMQRY request to query one or more uniquely named resources on a resource structure.
CSLRMQRY parameters

**ECB=symbol**

*(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRM QRY before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).*

**LIST=symbol**

*(Required) - Specifies the query resource list built by the caller. Each list entry is a separate query request. The list length can vary, depending upon the number of list entries. The list contains a header and one or more list entries. The list entries must reside in contiguous storage. Each query list entry contains the following:*

- Resource name - the client-defined name of the resource. The resource name can be a wildcard name. If it is a wildcard name, all resources that match the wildcard name are returned.
- Resource type - the resource type is a client-defined physical grouping of resources on the resource structure. Valid values are 1-255.
- Query options (optional) - options that indicate special processing to perform for the query.
- Owner (optional) - the owner of the resource. If you specify the owner, the resource is returned only if the resource name and owner match a resource on the resource structure. Specify binary zeroes to omit the owner, and the query returns the owner name in the RQYO_OWNER field in the output list entry.
- User (optional) - a user field set by the caller, which is passed back in the output list entry associated with the input list entry.

**LISTLEN=symbol**

*(Required) - Specifies the 4-byte query resource list length.*

**OUTLEN=symbol**
OUTLEN=(r2-r12)
(Required) - Specifies a 4-byte field to receive the length of the output buffer returned by the CSLRMQRY request. OUTLEN contains the length of the output buffer pointed to by the OUTPUT parameter. The length of the output data (header and entries) is passed in the output header data, mapped by CSLRQRYO.

OUTPUT=output
OUTPUT=(r2-r12)
(Required) - Specifies a 4-byte field to receive the address of the variable length output returned by the CSLRMQRY request. The output contains a header and one or more query entries for resource queries that were attempted. The output length is returned in the OUTLEN field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The CSLRQRYO macro maps the output that is returned. The output contains a header and one or more list entries. The header contains the following:
- an eyecatcher
- the output length
- CSLRQRYO version
- CSLRQRYO header length (offset to start of entries)
- minimum entry length (offset to DATA2)
- resource entry count
- time stamp

Each output entry represents a resource query that was attempted. Each entry contains the following parameters:
- Output entry length - the list entry length can vary, depending upon whether DATA2 is returned.
- Name type - the name type is a client-defined value associated with a resource type that ensures uniqueness of client-defined resource names within a name type. Valid values are 1-255.
- Resource name - client-defined name of the resource.
- Resource type - the resource type is a client-defined physical grouping of resources on the resource structure. Valid values are 1-255.
- Version - the resource version, which is the number of times the resource has been updated.
- DATA2 flag byte - flag byte indicating if DATA2 was read.
- Resource name status flag - the resource name status indicates how the resource name in the query output list entry is associated with the input resource parameter. This enables you to tie the input resource parameter to the output query list entries that are generated. The following resource name status are possible:
  - Specific parameter
    A specific resource name was specified. This query list entry contains the resource name that matches the input parameter.
  - Wildcard Parameter
    A wildcard parameter was specified. This query list entry contains the wildcard parameter and a completion code. This query list entry does not contain information about a specific resource. If the completion code is zero, one or more wildcard match list entries follow.
  - Wildcard match
    A wildcard parameter was specified. This entry contains information
about one resource that matches the input wildcard parameter. All wildcard match list entries follow contiguously after a wildcard parameter list entry.

- **Owner** - owner of a resource.
- **DATA1** - a small piece of client data (fixed length, contained in the adjunct area of a data entry) associated with an existing resource.
- **DATA2 length** - length of a large piece of client data associated with an existing resource, if DATA2 exists and the option to read DATA2 was set.
- **Optional User field** - optional 4 byte user field passed back to the caller in the output list entry associated with the input list entry.
- **DATA2** - a large piece of client data (variable length, contained in one or more data elements of a data entry) associated with an existing resource, if DATA2 exists, and the option to read DATA2 was set. The maximum size of DATA2 is 61312 bytes (X'EF80').
- **Completion code for the query request** - completion codes are mapped by CSLRRR. Possible completion codes are:

  `X'00000000'`
  Query request succeeded. At least one resource matching the query parameters is returned in the output buffer specified by OUTPUT=.

  `X'00000004'`
  No resources found.

  `X'00000008'`
  Invalid resource type.

  `X'0000000C'`
  Invalid name type.

  `X'00000024'`
  Resource structure is unavailable.

  `X'00000034'`
  Invalid options specified.

  `X'00000038'`
  Query failed because of CQS internal error.

  `X'0000003C'`
  Query failed because RM incorrectly built the CQSBRWSE list entry.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the query output. It is the caller’s responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is through with the storage. The length of the buffer is returned in the OUTLEN= field.

**PARM**=`symbol`
**PARM**=`(r2-r12)`

(Required) - Specifies the CSLRMQRY parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RQRY_PARMLEN.

**PROTOCOL=RQST**

(Optional) - SCI protocol for sending the request to RM. RQST sends the query request using SCI request interface.

**RETCODE**=`symbol`
RETCODE=(r2-r12)  
(Required) - specifies a 4-byte field to receive the return code on output. RM return codes are defined in CSLRRR. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

RETNAMES=symbol
RETNAMES=(r2-r12)  
(Optional) - Specifies an 8-byte field to receive the RM name returned to the caller. This is the CSL member name of the target RM address space to which SCI sent the request.

RETTOKEN=symbol
RETTOKEN=(r2-r12)  
(Optional) - Specifies a 16-byte field to receive RM's SCI token returned to the caller. This is the SCI token for the target RM address space to which SCI sent the request.

RSNCODE=symbol
RSNCODE=(r2-r12)  
(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRRR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

SCITOKEN=symbol
SCITOKEN=(r2-r12)  
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

### CSLRMQRY return and reason codes

The following table lists the return and reason codes that can be returned on a CSLRMQRY request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>

"Issue CSL RM requests to manage global resources” on page 184

CSLRMREG: register clients

You use the CSLRMREG request to register a client to RM and, optionally, to register the client’s resource types and associated name types. The client being registered to RM must be authorized to issue a CSLRMREG request. However, you cannot register a client if an IMSplex-wide process is in progress.

You must register a client to RM before the client can issue any other RM requests. After the client is registered, it must participate in any IMSplex-wide processes that are performed. You must register the client to all RMs that are active in the IMSplex. If registration to an RM fails, you must deregister the client from any RMs to which the client had successfully registered. If an RM fails, register with it when it restarts.

You can register the same client multiple times. For example, you might need to specify the resource list for the client after the client is already registered. Optionally, register resource types to RM along with the client to define the resource types to RM and associate a name type with each resource type. You must register resource types before you can specify them in other requests. You cannot register the client if the resource type and name type associations do not match those already registered previously.

Resource-processing clients, such as the IMS control region, issue this request.

This request is supported in assembler language.
CSLRMREG syntax

CSLRMREG DSECT syntax

Use the DSECT function of a CSLRMREG request to include the following inputs and outputs in your program:
- Equate (EQU) statements for the length of the CSLRMREG parameter list
- The CSLRMREG return codes, reason codes, and completion codes
- The CSLRREGL DSECT to map the input registration list
- The CSLRREGO DSECT to map the register output

CSLRMREG REGISTER syntax

Use the CSLRMREG request to register a client to RM and, optionally, to register the client’s resource types and associated name types to RM.

CSLRMREG parameters

ECB=symbol
ECB=(r2-r12)
(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRMREG before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).

LIST=symbol
LIST=(r2-r12)
(Optional) - Specifies the registration list built by the caller. Each list entry is a separate resource type registration. If a registration list is specified when no resource structure is defined, it is ignored.

The CSLRREGL macro maps the registration list entry. The list contains a header and one or more list entries. The list entries must reside in contiguous storage. Each registration list entry contains the following:
- Resource type
- Name type

LISTLEN=symbol
LISTLEN=(r2-r12)
(Optional) - Specifies the 4-byte registration list length. LISTLEN is required if LIST is specified.
OUTLEN=\textit{symbol}  
\textbf{OUTLEN=(r2-r12)}  
(Required) - Specifies a 4-byte field to receive the length of the output returned by the CSLRMREG request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.

The output length is zero if no output is built, for example, if an error is detected before any output can be built.

OUTPUT=\textit{output}  
\textbf{OUTPUT=(r2-r12)}  
(Required) - Specifies a 4-byte field to receive the address of the variable length output returned by the CSLRMREG request. The output contains a header and zero, one, or more registration entries for registrations that were attempted. The output length is returned in the OUTLEN= field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The CSLRREGO macro maps the output that is returned. The output contains a header and zero, one, or more list entries. The output header contains the following:

- Eyecatcher
- Output length
- CSLRREGO version
- CSLRREGO header length (offset to start of entries)
- CSLRREGO entry length
- Registration list count
- Time stamp
- Registration status
- Structure version

Each output entry represents a registration request that was attempted. Each entry contains the following:

- Resource type
- Name type
- Completion code for the registration request. Completion codes are mapped by CSLRRR. Possible completion codes are:

\texttt{X'00000000'}

Register succeeded.

\texttt{X'00000008'}

Invalid resource type. The resource type cannot be zero.

\texttt{X'0000000C'}

Invalid name type. The name type cannot be zero, or the resource type is already defined with a different name type.

\textbf{PARM=\textit{symbol}}  
\textbf{PARM=(r2-r12)}  
(Required) - Specifies the CSLRMREG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RREG_PARMLN.

\textbf{RETCODE=\textit{symbol}}  
\textbf{RETCODE=(r2-r12)}  
(Required) - Specifies a 4-byte field to receive the return code on output.
return codes are defined in CSLRR. SCI return codes are defined in CSLSRR.
Possible return codes are described in the following table.

**RMNAME=symbol**
**RMNAME=(r2-r12)**
(Required) - Specifies an 8-byte RM name to which to send the registration request.

**RSNCODE=symbol**
**RSNCODE=(r2-r12)**
(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=symbol**
**SCITOKEN=(r2-r12)**
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSREG FUNC=REGISTER request.

### CSLRMREG return and reason codes

The following table lists the return and reason codes that can be returned on a CSLRMREG request. Also included is the meaning of a reason code (that is, what possibly caused it).

**Table 57. CSLRMREG return and reason codes**

**CSLRMUPD: update resources**

By issuing the CSLRMUPD request, you can create a resource if it does not exist, or update a resource if it does exist (as long as the version specified matches the version of the resource). A resource can be created or updated with or without client data.

This request is supported in assembler language.

**CSLRMUPD syntax**

**CSLRMUPD DSECT syntax**

Use the DSECT function of a CSLRMUPD request to include the following inputs and outputs in your program:

- Equate (EQU) statements for the length of the CSLRMUPD parameter list
- The CSLRMUPD return codes, reason codes, and completion codes
- The CSLRUPDL DSECT to map the input update list
- The CSLRUPDO DSECT to map the update output

```plaintext
CSLRMUPD—FUNC=DSECT
```

**CSLRMUPD UPDATE syntax**

Use the CSLRMUPD request to create or update a uniquely named resource on a resource structure.

```plaintext
CSLRMUPD—FUNC=UPDATE—PARM=parm—LIST=updlist—LISTLEN=updlistlength
OUTPUT=output—OUTLEN=outputlength—ECB=ecb—RETNAME=returnname
```
CSLRMUPD parameters

**ECB=** symbol
**ECB=(r2-r12)**
(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the request must issue a WAIT (or equivalent) after receiving control from CSLRM UPD before using or examining any data returned by this request (including the RETCODE and RSNCODE fields).

**LIST=** symbol
**LIST=(r2-r12)**
(Required) - Specifies the update resource list built by the caller. Each list entry is a separate update request. The list length can vary, depending upon the number of list entries and whether they contain DATA2.

The CSLRUPDL macro maps the update resource list entry. The list contains a header and one or more list entries. The list entries must reside in contiguous storage. Each update list entry contains the following:

- Entry length - the update list entry length. The list entry length can vary, depending upon whether DATA2 is specified.
- Resource name - client-defined name of the resource.
- Resource type - the resource type is a client-defined physical grouping of resources on the resource structure. Valid values are 1-255.
- Update options - options that indicate special processing to perform for the update.
- Version - the resource version, which is the number of times the resource has been updated. The version must match the resource’s version for an existing resource for the update to succeed. The version must be zero to create a resource.
- Owner - owner of the resource.
- DATA1 - a small piece of client data (fixed length, contained in the adjunct area of a data entry) for the resource to be updated.
- DATA2 length - DATA2 length, if DATA2 is specified.
- DATA2 - a large piece of client data (variable length, contained in one or more data elements of a data entry) associated with the resource to be updated. DATA2 is optional. The maximum size of DATA2 is 61312 bytes (X'EF80').

**LISTLEN=** symbol
**LISTLEN=(r2-r12)**
(Optional) - Specifies the 4-byte update resource list length. LISTLEN is required if LIST is specified.

**OUTLEN=** symbol
**OUTLEN=(r2-r12)**
(Required) - Specifies a 4-byte field to receive the length of the output returned by the CSLRMUPD request. OUTLEN contains the length of the output pointed to by the OUTPUT= parameter.
The output length is zero if no output is built, for example, if an error is detected before any output can be built.

\textbf{OUTPUT=\textit{output}}

\textbf{OUTPUT=(r2-r12)}

(Required) - Specifies a 4-byte field to receive the address of the variable length output returned by the CSLRMUPD request. The output contains a header and one or more update entries for resource updates that were attempted. The output length is returned in the OUTLEN= field.

The output address is zero if no output was built, for example, if an error was detected before any output could be built.

The CSLRUPDO macro maps the output that is returned. The output contains a header and one or more list entries. The output header contains the following:

- Eyecatcher
- Output length
- CSLRUPDO version
- Time stamp
- Resource entry count
- CSLRUPDO header length (offset to start of entries)
- Minimum entry length (offset to DATA2)

Each output entry represents a resource update that was attempted. Each entry contains the following:

- Output entry length - the list entry length can vary, depending upon whether DATA2 is returned.
- Resource type
- Name type - the name type is a client-defined value associated with a resource type that ensures uniqueness of client-defined resource names within a name type. Valid values are 1-255.
- Resource name
- Version - new resource version, if update succeeded, or the resource version of an existing resource, if the failed because of a version mismatch.
- Owner - resource owner of an existing resource, if the update failed because of a version mismatch and the option to read the owner was set.
- DATA1 - a small piece of client data (fixed length, contained in the adjunct area of a data entry) associated with an existing resource, if the update failed because of a version mismatch and the option to read DATA1 was set.
- DATA2 length - length of large piece of client data associated with an existing resource, if the update failed because of a version mismatch, DATA2 exists, and the option to read DATA2 was set.
- DATA2 - a large piece of client data (variable length, contained in one or more data elements of a data entry) associated with an existing resource, if the update failed because of a version mismatch, DATA2 exists, and the option to read DATA2 was set. The maximum size of DATA2 is 61312 bytes (X'EF80').
- Completion code for the update request - completion codes are mapped by CSLRRR. Possible completion codes are:

\textbf{X'00000000'}

Update request succeeded.
X'00000008'  
Invalid resource type.

X'00000010'  
Version mismatch. Resource already exists and version specified on input did not match.

X'00000014'  
Resource already exists as a different resource type.

X'00000018'  
Resource type is not registered. The resource type must be registered using a CSLRMREG request.

X'0000001C'  
Resource structure is full.

X'00000024'  
Resource structure is unavailable.

X'00000038'  
Update failed because of CQS internal error.

X'0000003C'  
Update failed because RM incorrectly built the CQSUPD list entry.

X'00000040'  
Version mismatch. The resource already exists and the version specified on input did not match. The requestor requested that DATA2 be passed back, but RM encountered an error reading DATA2.

The output buffer is not preallocated by the caller. After the request returns it, this word contains the address of a buffer containing the update output. It is the caller's responsibility to release this storage by issuing the CSLS CBFR FUNC=RELEASE request when it is through with the storage. The length of the output is returned in the OUTLEN= field.

**PARM=**

**PARM=(r2-r12)**  
(Required) - Specifies the CSLRMUPD parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by RUPD_P ARMLN.

**RETCODE=**

**RETCODE=(r2-r12)**  
(Required) - specifies a 4-byte field to receive the return code on output. RM return codes are defined in CSLRRR. SCI return codes are defined in CSLSRR. Possible return codes are described in the following table.

**RETTOKEN=**

**RETTOKEN=(r2-r12)**  
(Optional) - Specifies a 16-byte field to receive RM's SCI token returned to the caller. This is the SCI token for the target RM address space to which SCI sent the request.

**RSNCODE=**

Chapter 7. Writing a CSL RM client  215
**RSNCODE=(r2-r12)**

(Required) - Specifies a 4-byte field to receive the reason code on output. RM reason codes are defined in CSLRRR. SCI reason codes are defined in CSLSRR. Possible reason codes are described in the following table.

**SCITOKEN=symbol**

SCITOKEN=(r2-r12)

(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSREG FUNC=REGISTER request.

---

**CSLRMUPD return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLRMUPD request. Also included is the meaning of a reason code (that is, what possibly caused it).

CSL RM directives

An RM directive is a function that RM defines that can be sent as a message to RM clients, informing the RM clients of work to be processed. After a resource processing client is registered to RM, RM can direct that client to perform RM functions, or directives, by issuing the CSLSCMSG request. A resource processing client is any system that manages resources and uses RM to manage global information about those resources.

RM directives are always issued in message protocol (PROTOCOL=MSG), that is, asynchronously; RM therefore expects no response from the RM client, and it continues processing without waiting for a response. The RM client is responsible for determining whether or not to take any action in response to the directive. If the client does not respond, the directive times out.

The CSLRMDIR macro maps the RM directives. The SCI Input exit routine’s INXP_MBRPLPTR field points to the CSLRMDIR parameter list. The following RM directives are defined in the CSLRMDIR macro:
- Repopulate structure (RDIR_STRPOPD)
- Structure failed (RDIR_STRFAILD)
- Process step (RDIR_PRSTEPD)
• Process step response (RDIR_PRRESPD)

**Related reference:**

[CSL SCI Input exit routine (Exit Routines)]

---

**CSL RM repopulate structure directive**

The repopulate structure directive is sent to all resource processing clients after an RM detects a structure failure and the structure is reallocated. The client then repopulates the structure and can receive this directive from all RMs that it is registered to.

If the client receives directives from multiple RMs to repopulate the structure after having already done so, it can ignore those requests after confirming that the directives apply to the same structure name and version.

**Repopulate structure parameters**

</thead>
<tbody>
<tr>
<td>Contains the length of the repopulate structure.</td>
</tr>
</tbody>
</table>

---

**CSL RM structure failed directive**

The structure failed directive is sent to a resource processing client when the resource structure fails and cannot be reallocated. The client cannot make any more resource requests until the problem is corrected.

A client can receive this directive from all RMs to which it is registered. If the client receives directives from multiple RMs, it can ignore duplicate requests after confirming that the directives apply to the same structure name and version.

**Structure failed parameters**

<tr>
<th><strong>RDIR_SFVERPTR</strong>=<strong>address</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Contains the address of the structure version.</td>
</tr>
</tbody>
</table>
**RDIR_STRFAILN=length**
Contains the length of the structure failed directive.

**CSL RM process step directive**
The Process Step directive is sent to a resource processing client when a process step needs to be performed.

**Process step parameters**

**RDIR_PRSTEP**
Identifies the start of the Process Step directive.

**RDIR_PSTKNLEN=length**
Contains the length of the process token (PRCTOKEN), which uniquely identifies the IMSplex-wide process. PRCTOKEN is returned after the CSLRMPRI FUNC=INITIATE request successfully completes. PRCTOKEN can be specified on CSLRMPRS FUNC=PROCESS, CSLRMPRR FUNC=RESPOND, and CSLRMPRT FUNC=TERMINATE requests.

**RDIR_PSTKNPTR=address**
Contains the address of the PRCTOKEN.

**RDIR_PSUOWLEN=length**
Contains the length of the UOWTOKEN, a client-defined UOW that uniquely identifies a process instance. UOWTOKEN also unites the PROCESS INITIATE, PROCESS RESPOND, and PROCESS TERMINATE steps. UOWTOKEN is defined by the CSLRMPRI FUNC=INITIATE request and can be specified on CSLRMPRS FUNC=PROCESS requests.

**RDIR_PSUOWPTR=address**
Contains the address of the UOWTOKEN.

**RDIR_PRCNMLEN=length**
Contains the length of the process name (PRCNAME), which is defined by the CSLRMPRI FUNC=INITIATE request. It can also be specified on the CSLRMPRS FUNC=PROCESS and CSLRMPRT FUNC=TERMINATE requests.

**RDIR_PRCNMPT=address**
Contains the address of the PRCNAME.

**RDIR_PRCTYPE**
The process type is defined by the CSLRMPRI FUNC=INITIATE request. It can be specified on the CSLRMPRS FUNC=PROCESS and CSLRMPRT FUNC=TERMINATE requests. This parameter is passed by value; the length field is always zero.

**RDIR_PSNAM**
Contains the process step name, which is defined by the CSLRMPRS FUNC=PROCESS request. This parameter is passed by value; the length field is always zero.

**RDIR_PSDATLEN=length**
Contains the length of the process step client data (CDATALEN). The client data is passed to the participants in the process step. CDATALEN is specified on the CSLRMPRS FUNC=PROCESS request.

**RDIR_PSDATPTR=address**
Contains the address of the process step client data (CDATA).
RDIR_CNAMLEN=\textit{length}
Contains the length of the client name that was registered to SCI by the client that originated the process step (the process step master).

RDIR-CNAMPTR=\textit{address}
Contains the address of the client name that was registered to SCI by the client that originated the process step (the process step master).

RDIR_CTYPE
Identifies the client type that was registered to SCI by the client that originated the process step (the process step master). This parameter is passed by value; the length field is always zero.

RDIR_CSTYPLEN
Contains the length of the client subtype that was registered to SCI by the client that originated the process step (the process step master).

RDIR_CSTYPADDR
Contains the address of the client subtype that was registered to SCI by the client that originated the process step (the process step master).

RDIR_PRSTEPLN
Contains the length of the process step directive.

\section*{CSL RM process step response directive}
The Process Step Response directive is sent to RM by a client that is responding to a process step with a CSLRMPRR request.

\subsection*{Process step response parameters}

RDIR_PRRESP
Identifies the start of the process step response directive.

RDIR_PRTKNLLEN=\textit{length}
Contains the length of the process token (PRCTOKEN), which uniquely identifies the IMSplex-wide process. PRCTOKEN is returned after the CSLRMPRI FUNC=INITIATE request successfully completes. PRCTOKEN can be specified on CSLRMPRS FUNC=PROCESS, CSLRMPRR FUNC=RESPOND, and CSLRMPRT FUNC=TERMINATE requests.

RDIR_PRTKNPTR=\textit{address}
Contains the address of the PRCTOKEN.

RDIR_PROUTLEN=\textit{length}
Contains the length of the process step response output (OUTPUT). The response output is passed back to the originator of the process step. OUTPUT is specified on the CSLRMPRR FUNC=RESPOND request.

RDIR_PROUTPTR=\textit{address}
Contains the address of the response output (OUTPUT).

RDIR_PRCLEN=\textit{length}
Contains the process step response return code (RQSTRC). The return code is specified by the CSLRMPRR FUNC=RESPOND request.

RDIR_PRCPTR=\textit{address}
Contains the address of the process step response return code (RQSTRC).

RDIR_PRSNLEN=\textit{length}
Contains the length of the process step response reason code (RQSTRSN), which is specified by the CSLRMPRR FUNC=RESPOND request.
**RDIR_PRRSNPTR=address**

Contains the address of the process step response reason code (RQSTRSN).
Chapter 8. Writing a CSL SCI client

You must establish a connection to SCI (Structured Call Interface) in order to write a program that participates in an IMSplex (such as an AOP) and allows your IMSplex member to communicate with other IMSplex members. Without a connection to SCI, a program cannot participate in an IMSplex and communicate with other IMSplex members.

To establish a connection with SCI, you can use a subset of the SCI requests. These requests establish or terminate a connection with SCI and optionally indicate to SCI that the IMSplex member is in a ready state. When a member is in a ready state, it can have requests and messages routed to it by type.

SCI requests are also used by an IMSplex member to communicate with other IMSplex members and to find out information about those members. IMSplex members communicate with other members by using SCI requests to send messages, requests, and responses to requests. A query request can be used to find out information about the other members of the IMSplex.

Related reference:
“CSLSCQRY: query request” on page 235

Sequence of CSL SCI requests

Structured Call Interface (SCI) requests must be issued in a particular sequence in order to successfully register to SCI, ready the member, release storage allocated for the member, quiesce the member, and deregister the member from SCI.

The first SCI request is CSLSCREG. The member can then issue CSLSCRDY to tell SCI that it is ready to receive messages and requests that are routed by member type. If a member has storage that is allocated by SCI (for example, a message or an SCI allocated output parameter is received), the SCI buffer release request, CSLSCBFR, is issued to release the storage.

When a member is ready to terminate, the SCI quiesce request, CSLSCQSC, is used to tell SCI that the member does not want to receive messages and requests that are routed by member type. After the SCI deregistration request, CSLSCDRG, is used to terminate the connection with SCI, the member can no longer participate in the IMSplex.

The following table lists the sequence of requests issued by an SCI client. The request is listed with its purpose.

Table 59. Sequence of requests for SCI client

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSLSCREG</td>
<td>Register to SCI, which establishes the connection with SCI and enables the member to communicate within the IMSplex.</td>

<tr>
<td>CSLSCQSC</td>
<td>Quiesces the member to SCI, which tells SCI not to route messages and requests that are routed by member type to this member.</td>
</tr>
<tr>
<td>CSLSCDRG</td>
<td>Deregisters the member from SCI which ends the member's connection with SCI.</td>
</tr>
</tbody>
</table>

Advanced CSL SCI requests

After connecting to Structured Call Interface (SCI), an IMSplex member can use advanced SCI requests to request services from and find out information about other IMSplex members. Each advanced request has its own purpose.

After establishing the connection with SCI, an IMSplex member can use advanced SCI requests to:

- Communicate, or request services, from other IMSplex members.
  
  A message protocol and a request protocol are provided to facilitate communication among IMSplex members. A message is a one-way communication with another IMSplex member. A request requires that a response be returned to the requesting member.

- Find out information about the other members in the IMSplex.
  
  A query request, CSLSCQRY, allows an IMSplex member to find out who the other members of the IMSplex are and to obtain information about those IMSplex members.

The following table lists the advanced SCI requests with their purpose. These requests can be issued without regard to sequence; however, the IMSplex member issuing the request must have registered to SCI.

Table 60. Advanced SCI requests for IMSplex members

<table>
<thead>
<tr>
<th>Request</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSLSCMSG</td>
<td>Sends a one-way message to another IMSplex member.</td>
</tr>
<tr>
<td>CSLSCRQS</td>
<td>Sends a request to another IMSplex member. SCI expects a response to the request.</td>
</tr>
<tr>
<td>CSLSCQRY</td>
<td>Sends a response to a previously issued request.</td>
</tr>
<tr>
<td>CSLSCQRY</td>
<td>Issues a query to SCI to find out information about members of the IMSplex.</td>
</tr>
</tbody>
</table>

CSL SCI requests

SCI requests can be issued by an IMSplex member. Any member can also receive messages from any other IMSplex member after a connection is established.

Related concepts:

"CSL OM automated operator program clients" on page 139

CSLSCBFR: buffer return request

The CSLSCBFR request releases the storage that the Structured Call Interface (SCI) allocated for an IMSplex member. This storage is allocated to receive either an input message sent from another IMSplex member with the CSLSCMSG request, or an output parameter generated from a CSLSCRQS request.
Another macro can invoke the CSLSCRQS request as part of the code generated by the macro which, in turn, can return an SCI data type. The storage allocated for these parameters must be released with the CSLSCBFR macro. The CSLSCQRY macro is an example of an SCI macro that does this. The OUTPUT parameter specifies the address in storage to receive the address of the buffer that contains the output from the CSLSCQRY macro. Release this storage by using the CSLSCBFR request.

**Syntax**

*DSECT syntax*

Use the DSECT function of a CSLSCBFR request to include equate (EQU) statements in your program for the CSLSCBFR parameter list length and the CSLSCBFR request return and reason codes.

```
CSLSCBFR—FUNC=DSECT
```

**RELEASE syntax**

Use the RELEASE function of the CSLSCBFR request to release an SCI message buffer or SCI data type buffer. The SCI data type buffer is used for selected output parameters of the CSLSCRQS request for which SCI allocates storage.

```
CSLSCBFR—FUNC=RELEASE—PARAM=parm—SCITOKEN=scitoken—BUFFER=buffer—BUFFERPTR=buffer
RET CODE=returncode—RSNCODE=reasoncode
```

For messages generated from a CSLSCMSG request, the buffer address is the address of the member parameter list that is specified to the member input exit in the INXP_MBRPLPTR field in the input exit parameter list.

For a response generated from a CSLSCRQS request that uses an SCI data type buffer, the storage is allocated when the request is returned to the IMSplex member that initiated the original request. The buffer address is the address of this storage, which is returned in the field specified by the member on the request.

After the CSLSCBFR request is complete, the storage contained in the message buffer or request response is no longer accessible by the IMSplex member.

For non-authorized members, the storage must be released from a TCB that is under the JOBSTEP TCB from which the SCI registration call was made. The release fails if it is done from a TCB that is not under the registered JOBSTEP TCB.

**Parameters**

- **BUFFER=symbol**
  - 4-byte parameter that contains the address of a buffer that is to be released.
  - Either BUFFER or BUFFERPTR is required.
- **BUFFER=parm—SCITOKEN=scitoken—BUFFER=buffer—BUFFERPTR=buffer**
- **RET CODE=returncode—RSNCODE=reasoncode**
BUFFERPTR=(r1-r12)
  4-byte parameter that contains the address of a word in storage that contains
  the address of the buffer that is to be released.

  Either BUFFER or BUFFERPTR is required.

PARM=symbol
PARM=(r1-r12)
  Specifies the CSLSCBFR parameter list. The length of the parameter list must
  be equal to the parameter list length EQU value defined by SBFR_PARMLN.

RETCODE=symbol
RETCODE=(r1-r12)
  Specifies a 4-byte field to receive the return code on output. The SCI return
  codes are defined in CSLSRR. Possible return codes for CSLSCBFR are
  described in the following table.

RSNCODE=symbol
RSNCODE=(r1-r12)
  Specifies a 4-byte field to receive the reason code on output. The SCI reason
  codes are defined in CSLSRR. Possible reason codes for CSLSCBFR are
  described in the following table.

SCITOKEN=symbol
SCITOKEN=(r1-r12)
  Specifies a 16-byte field containing the SCITOKEN. This token uniquely
  identifies this IMSplex member's connection to SCI. The SCI token was
  returned by a successful CSLSCREG FUNC=REGISTER request.

Return and reason codes

The following table lists the return and reason codes that can be returned on a
CSLSCBFR macro request.

Table 61. CSLSCBFR request return and reason codes

<table>

</tbody>
</table>

CSLSCDRG: deregistration request

By issuing the CSLSCDRG request, you can terminate the connection between the
IMSplex member and SCI. After successful completion of this request, the SCI
token is no longer valid.
To make subsequent SCI requests, the IMSplex member must create a new connection with SCI with a CSLSCREG request.

**CSLSCDRG syntax**

**CSLSCDRG DSECT syntax**

Use the DSECT function of a CSLSCDRG request to include equate (EQU) statements in your program for the CSLSCDRG parameter list length and the CSLSCDRG return and reason codes.

\[\text{CSLSCDRG---FUNC=DSECT}\]

**CSLSCDRG DEREGISTER syntax**

The CSLSCDRG FUNC=DEREGISTER request deregisters the IMSplex member from SCI. After successful completion of the CSLSCDRG FUNC=DEREGISTER request, the SCITOKEN is invalid.

\[\text{CSLSCDRG---FUNC=DEREGISTER---PARAM=parm---SCITOKEN=scitoken}\]

\[\text{RETCODE=returncode---RSNCODE=reasoncode}\]

**CSLSCDRG parameters**

PARM=\textit{symbol}

\(\text{PARM=(r1-r12)}\)

(Required) - Specifies the CSLSCDRG parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by SDRG_LN.

RETCODE=\textit{symbol}

\(\text{RETCODE=(r1-r12)}\)

(Required) - Specifies the address of a 4-byte field to receive the CSLSCDRG return code. The SCI return codes are defined in CSLSRR. Possible return codes for CSLSCDRG are described in the following table.

RSNCODE=\textit{symbol}

\(\text{RSNCODE=(r1-r12)}\)

(Required) - Specifies the address of a 4-byte field to receive the CSLSCDRG reason code. The SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCDRG are described in the following table.

SCITOKEN=\textit{symbol}

\(\text{SCITOKEN=(r1-r12)}\)

(Required) - Specifies a 16-byte field containing the SCITOKEN. This token uniquely identifies this IMSplex member's connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

**CSLSCDRG return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLSCDRG macro request. Also included is the meaning of a reason code (that is, what possibly caused it).
Table 62. CSLSCDRG return and reason codes

**CSLSCMSG: send message request**

By issuing the CSLSCMSG request, you can send a message to one or more other IMSplex members. The target members are specified by SCITOKEN, member name, or member type.

**CSLSCMSG syntax**

**CSLSCMSG DSECT syntax**

Use the DSECT function of a CSLSCMSG request to include equate (EQU) statements in your program for the CSLSCMSG parameter list length, the IMSplex types and the CSLSCMSG return and reason codes.

```
---->CSLSCMSG--FUNC=DSECT---->
```

**CSLSCMSG SEND MESSAGE syntax**

The syntax of the CSLSCMSG FUNC=SEND request is shown below:

```
---->CSLSCMSG--FUNC=SEND--SCITOKEN=scitoken--PARM=parm--MBRPARM=mbrparmlist---->
---->MBRPCNT=mbrparmcount--MBRFUNC=mbrfunctioncode---->
---->MBRFSFUNC=mbrsubfunctioncode--FUNCTYPE=DEST---->FUNCTYPE=SENDER---->
```
CSLSCMSG parameters

**FUNCTION=SENDER**

**FUNCTION=DEST**

(Optional) - Specifies that the MBRFUNC and MBRSFUNC are defined by the DEST (destination) of this message or the SENDER of the message. This indicator is passed to the recipient of the message in the SCI Input exit parameter list.

**LISTLEN=<numeric literal>**

**LISTLEN=symbol**

**LISTLEN=(r1-r12)**

(Required if NAMELIST, TOKENLIST or TYPELIST is specified) - Specifies the length of the routing list. The routing list consists of a header and one or more list entries, each entry describing a single message destination (NAMELIST and TOKENLIST) or set of destinations (TYPELIST).

If LISTLEN is a numeric literal, all characters must be numbers. If any character is alphabetic, the parameter will be considered a symbol.

**MBRFUNC=symbol**

**MBRFUNC=(r1-r12)**

(Required) - Specifies a 4-byte member function code that is passed to the destination of the message in the SCI Input exit parameter list. This function code, along with the MBRSFUNC, identifies the message that is being sent.
If MBRFUNC is a symbol, the symbol points to a 4-byte area of storage that contains the function code.

**MBRPARM=symbol**

**MBRPARM=(r1-r12)**

(Required) - Specifies the address of a prebuilt parameter list. This parameter list must be built by the messaging module and consists of sets of pairs. Each pair describes a single parameter in the member parameter list and consists of the following:

- **parameter length**
  Four-byte parameter that specifies the length of the member parameter.

- **parameter address**
  Four-byte parameter that specifies the address of the member parameter.

The two methods for passing parameters in a parameter list are *by address* and *by value*. Both of these methods can be used when passing parameters in a CSLSCMSG request. The pair must be setup so that SCI will handle the parameter properly.

- **By address**
  To pass a parameter by address, the address of the parameter must be passed in *parameteraddress* and the length of the parameter must be passed in *parameterlength*. SCI will obtain the parameter from *parameteraddress*.

- **By value**
  To pass a parameter by value, the parameter must be passed in *parameteraddress* and zero must be passed in *parameterlength*. When the length is zero, SCI will copy the value contained in *parameteraddress* to the destination.

**Member Parameter List:** The user parameters specified here are presented to the IMSplex member that receives the message in the member parameter list, the address of which is contained in the Input exit parameter area field INXP_MBRPLPTR. Each parameter is represented by eight bytes, the first four bytes contain *parameterlength* and the second four bytes contain *parameteraddress* (if *parameteraddress* is an address, the second four bytes point to storage in the local address space, not the requesting address space).

**Null Parameters:** In some cases, the message processing module expects a set number of parameters with a defined order. If a message is to be sent that does not contain all the parameters, null parameters must be sent to ensure the data buffer contains everything that is expected. Null parameters can be sent by specifying zero for *parameterlength* and *parameteraddress*. The eight bytes that represent the parameter in the data buffer will contain zeros.

**MBRPCNT=symbol**

**MBRPCNT=(r1-r12)**

(Required) - Specifies a 4-byte field that contains the number of member parameters that are included in MBRPARM.

**MBRSFUNC=symbol**

**MBRSFUNC=(r1-r12)**

(Optional) - Specifies a 4-byte member subfunction code that is passed to the destination of the message in the SCI Input exit parameter list. This subfunction code, along with the MBRFUNC, identifies the message that is being sent.
If MBRSFUNC is a symbol, the symbol points to a 4-byte area of storage that contains the subfunction code.

**NAME=symbol**

**NAME=(r1-r12)**

(Optional) - Specifies the address of an 8-byte member name of the destination of this message. This name can be obtained from the Notify exit (when the member joins the IMSplex) or by issuing a CSLSCQRY message.

**Note:** One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

To route by NAME, the destination member must be authorized. If the member is not authorized, the message is not sent.

**NAMELIST=symbol**

**NAMELIST=(r1-r12)**

(Optional) - Specifies the address of a list of member names to which this message is to be routed. This list consists of a header and one or more list entries, each entry defining a single member name.

**Note:** One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

The list header DSECT is CSLSMGLH, and the list entry DSECT is CSLSNMLE. These DSECTs are defined in CSLSCMAP.

For a message to be routed to a member using NAMELIST, that member must be an authorized member. If a member name for a non-authorized member is included in NAMELIST, the name will not be found and the message will not be sent to that member.

The NAMELIST is sent to SCI for processing. Then, control is returned to your program. A response of “Request completed successfully” does not mean that the message was sent to all names in the list; it means that the list was successfully sent to SCI. Errors could occur while the list is processed and the message is sent. Possible errors include:

- Name not found
- Name found, but the member terminated before message is sent
- SCI abended

These errors are not returned to your program.

**PARM=symbol**

**PARM=(r1-r12)**

(Required) - Specifies the address of a parameter list used by the message to pass the parameters to SCI. The length of the storage must be at least equal to the value of SMSG_LN. The storage must begin on a word boundary.

**RETCODE=symbol**

**RETCODE=(r1-r12)**

(Required) - Specifies the address of a 4-byte field to receive the CSLSCMSG return code. The SCI return codes are defined in CSLSRR.

**RETNAM=symbol**

**RETNAM=(r1-r12)**

(Optional) - Specifies the address of an 8-byte field to receive the name of the IMSplex member to which the message was sent. If the message is sent to more than one destination, nothing is returned in this field.

**RETTOKEN=symbol**
RETTOKEN=(r1-r12)
(Optional) - Specifies the address of an 8-byte field to receive the token of the IMSplex member to which the message was sent. If the message is sent to more than one destination, nothing is returned in this field.

ROUTE=ANY
ROUTE=ALL
ROUTE=LOCAL
(Optional) - Specifies how the message should be routed to the type specified in the TYPE parameter or the types specified in the TYPELIST parameter. This parameter is valid only if TYPE or TYPELIST is specified.

ANY
Routes the message to a single member of the types specified. SCI selects the member that will receive the message. TYPE=ANY is not valid with TYPELIST.

ALL
Routes the message to all members of the specified types.

LOCAL
Routes the message to all members of the specified types that are active on the local z/OS image.

RSNCODE=symbol
RSNCODE=(r1-r12)
(Required) - Specifies the address of a 4-byte field to receive the CSLSCMSG reason code. The SCI reason codes are defined in CSLSRR.

SCITOKEN=symbol
SCITOKEN=(r1-r12)
(Required) - Specifies the address of a 16-byte field that contains the SCI token of the member making the request. The token was returned on the CSLSCREG request.

TOKEN=symbol
TOKEN=(r1-r12)
(Optional) - Specifies the address of the 16-byte SCI token of the destination of this message. This token can be obtained from the Notify exit (when the member joins the IMSplex) or by issuing a CSLSCQRY message.

Note: One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

TOKENLIST=symbol
TOKENLIST=(r1-r12)
(Optional) - Specifies the address of a list of SCI tokens that represent members to which this message is to be routed. This list consists of a header and one or more list entries, each entry defining a single SCI token.

Note: One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

The list header DSECT is CSLSMGLH, and the list entry DSECT is CSLSTKLE. These DSECTs are defined in CSLSCMAP.

The TOKENLIST is sent to SCI for processing. Then, control is returned to your program. A response of “Request completed successfully” does not mean that the message was sent to all SCI tokens in the list; it means that the list was successfully sent to SCI. Errors could occur while the list is processed and the message is sent. Possible errors include:
• Token not found
• Token found but member terminated before message is sent
• SCI abended

These errors are not returned to your program.

`TYPE=` symbol
`TYPE=` 'AOP'
`TYPE=` 'BATCH'
`TYPE=` 'CQS'
`TYPE=` 'DBRC'
`TYPE=` 'IMS'
`TYPE=` 'IMSCON'
`TYPE=` 'ODBM'
`TYPE=` 'OM'
`TYPE=` 'OTHER'
`TYPE=` 'RM'
`TYPE=` 'SCI'

(Optional) - TYPE specifies the SCI type of the destination of this message. SCI routes the message to one or more members of the specified type (depending on the value of the route parameters). If there are no members of the specified type, an error is returned.

**Note:** One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

If this parameter is passed as a literal, the literal must be enclosed in single quotation marks. If this parameter is passed as a symbol or register, the symbol or register must contain the member type code. The member type code can be obtained by using the CSLSTPIX macro.

`TYPELIST=` symbol
`TYPELIST=` (r1-r12)

(Optional) - Specifies the address of a list of member types to which this message is to be routed. This list consists of a header and one or more list entries, each entry defining a single SCI token.

**Note:** One of the routing parameters (NAME, TOKEN, TYPE, NAMELIST, TOKENLIST or TYPELIST) must be included.

The list header DSECT is CSLSMGLH, and the list entry DSECT is CSLSTPLE. These DSECTs are defined in CSLSCMAP.

The TYPELIST is sent to SCI for processing. Then, control is returned to your program. A response of “Request completed successfully” does not mean that the message was sent to all types in the list; it means that the list was successfully sent to SCI. Errors could occur while the list is processed and the message is sent. Possible errors include:

• No members of the specified type are active
• A member of the specified type was found but terminated before the message is sent
• SCI abended

These errors are not returned to your program.
## CSLSCMSG return and reason codes

The following table lists the return and reason codes that can be returned on a CSLSCMSG macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

CSLSCQRY: query request

By issuing the CSLSCQRY request, an IMSplex member can obtain information about the members of the IMSplex.

CSLSCQRY syntax

CSLSCQRY DSECT syntax

Use the DSECT function of a CSLSCQRY request to include equate (EQU) statements in your program for the CSLSCQRY parameter list length, the IMSplex types and the CSLSCQRY return and reason codes.

CSLSCQRY QUERY syntax

Use the following syntax to issue the CSLSCQRY service request. The output is returned to the caller when the request is complete.

A:

CSLSCQRY parameters

ECB=symbol

ECB=(r1-r12)

(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLSCQRY, before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).
OUTLEN=\textit{symbol}  
OUTLEN=(r1-r12)  
(Required) - Specifies a 4-byte field to receive the length of the output returned by the CSLSCQRY request. OUTLEN receives the length of the output pointed to by the OUTPUT= parameter.  
The output length is zero if no output is built, for example, if an error is detected before any output can be built.

OUTPUT=\textit{output}  
OUTPUT=(r1-r12)  
(Required) - Specifies a field to receive a pointer to the variable length output returned by the CSLSCQRY request. The output length is returned in the OUTLEN= field.  
The output address is zero if no output was built, for example, if an error was detected before any output could be built.  
The CSLSQRYO macro maps the output that is returned. The output contains a header and one or more list entries.  
The output buffer is not preallocated by the caller. After being returned by the request, this word contains the address of a buffer containing the query output. It is the caller's responsibility to release this storage by issuing the CSLSCBFR FUNC=RELEASE request when it is through with the storage.

PARM=\textit{symbol}  
PARM=(r1-r12)  
(Required) - Specifies the CSLSCQRY parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by SQRY_PARMLN.  

PROTOCOL=RQST  
(Optional) - SCI protocol for sending the request to SCI. RQST indicates that the SCI request interface protocol is to be used for the request.

RETCODE=\textit{symbol}  
RETCODE=(r1-r12)  
(Required) - Specifies the address of a 4-byte field to receive the CSLSCQRY return code. SCI return codes are defined in CSLSRR. Possible return codes for CSLSCQRY are described in the following table.  

RSCODE=\textit{symbol}  
RSCODE=(r1-r12)  
(Required) - Specifies a 4-byte field to receive the reason code on output. SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCQRY are described in the following table.  

SCITOKEN=\textit{symbol}  
SCITOKEN=(r1-r12)  
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSREG FUNC=REGISTER request.

SCOPE=\textit{IMSPLEX}  
SCOPE=\textit{LOCAL}  
SCOPE=\textit{TYPE}  
(Optional) - Specifies the scope of information that is being requested.  

\textbf{IMSPLEX}  
This option returns data for all of the members in the IMSPlex.
LOCAL
This option returns information for all of the members on the local z/OS image.

TYPE
This option returns information for all of the members that are of the specified IMSplex member type (and optionally subtype).

SUBTYPE=symbol
SUBTYPE=(r1-r12)
(Optional) - Four-byte input parameter that specifies the address of an 8-byte subtype that further qualifies the IMSplex member type about which information is being requested. This subtype is defined by the IMSplex member and was specified on the CSLSCREG request.

This parameter is valid only when SCOPE=TYPE.

TYPE=symbol
TYPE='AOP'
TYPE='BATCH'
TYPE='CQS'
TYPE='DBRC'
TYPE='IMS'
TYPE='IMSCON'
TYPE='ODBM'
TYPE='OM'
TYPE='OTHER'
TYPE='RM'
TYPE='SCI'
(Optional) - Specifies the IMSplex member type for which the query is being issued. SCI will return information for all of the members that are of the specified IMSplex member type (and, optionally, subtype). This parameter is required when SCOPE=TYPE.

If this parameter is passed as a literal, the literal must be enclosed in single quotation marks. If it is passed as a symbol, the symbol points to a word in storage that contains the code for the member type. If it is passed as a register, the register contains the member type code in the low-order half word of the register.

The code for the member type can be obtained by using the CSLSTPIX macro.

CSLSCQRY return and reason codes

The following table lists the return and reason codes that can be returned on a CSLSCQRY macro request. Also included is the meaning of a reason code (that is, what possibly caused it). In addition, CSLSCQRY can return any of the return codes listed in the following table.

Table 64. CSLSCQRY return and reason codes

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>Request completed successfully.</td>
</tr>
<tr>

CSLSCQSC: quiesce request
The SCI Quiesce request tells SCI to stop routing messages and requests that have been routed by TYPE to the issuing IMSplex member. After this request has successfully completed, the only messages and requests that are routed to the member are those that are routed directly by SCITOKEN or by NAME.

Note: Because of the asynchronous nature of the processes within the IMSplex and z/OS, messages and requests routed by TYPE might still be received by the IMSplex member after successful completion of the CSLSCQSC FUNC=QUIESCE request. The potential for this occurring is small, but it can happen. The IMSplex member must be able to handle a message or request coming in after the CSLSCQSC FUNC=QUIESCE has successfully completed.

CSLSCQSC syntax

CSLSCQSC DSECT syntax
Use the DSECT function of a CSLSCQSC request to include equate (EQU) statements in your program for the CSLSCQSC parameter list length and the CSLSCQSC return and reason codes.

►►CSLSCQSC—FUNC=DSECT◄◄

CSLSCQSC QUIESCE syntax
The CSLSCQSC FUNC=QUIESCE request quiesces the connection between SCI and the IMSplex member. After the successful completion of the request, only messages and requests that are routed directly by SCITOKEN or by NAME are sent to this IMSplex member.

►►CSLSCQSC—FUNC=QUIESCE—PARM=parm—SCITOKEN=scitoken—RETCODE=returncode◄◄
►►RSNCODE=reasoncode◄◄

CSLSCQSC parameters

PARM= symbol
PARM=(r1-r12) (Required) - Specifies the CSLSCQSC parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by SQSC_PARMLN.

RETCODE= symbol
RETCODE=(r1-r12) (Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSRR. Possible return codes for CSLSCQSC are described in the following table.

RSNCODE= symbol
RSNCODE=(r1-r12)
(Required) - Specifies a 4-byte field to receive the reason code on output. SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCQSC are described in the following table.

SCITOKEN=symbol
SCITOKEN=(r1-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

CSLSCQSC return and reason codes
The following table lists the return and reason codes that can be returned on a CSLSCQSC macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

Table 65. CSLSCQSC return and reason codes

“CSLSCMSG: send message request” on page 228

CSLSCRDY: ready request
The SCI ready request enables the IMSplex member to receive messages and requests that are routed by TYPE. After the CSLSCREG request is issued and until CSLSCRDY is issued, the IMSplex member can only receive requests that are routed directly to a single target address space. The IMSplex member can send messages and requests that are routed by any method.

Note: The IMSplex member must be ready to process messages and requests that have been routed by TYPE when CSLSCRDY is issued. Because of the asynchronous nature of an IMSplex, the member might receive a message or request that has been routed by TYPE before control is returned after issuing CSLSCRDY.

CSLSCRDY syntax

DSECT syntax
Use the DSECT function of a CSLSCRDY request to include equate (EQU) statements in your program for the CSLSCRDY parameter list length and the CSLSCRDY return and reason codes.

READY syntax
The CSLSCRDY FUNC=READY request tells SCI that the IMSplex member is now ready to receive messages and requests that are routed by an IMSplex member type.

```
>>> CSLSCRDY—FUNC=READY—SCITOKEN=scitoken—PARAM=parm—RETCODE=returncode
>>> RSNCODE=reasoncode
```

**CSLSCRDY parameters**

- **PARAM=symbol**
  - **PARAM=(r1-r12)**
    - (Required) - Specifies the CSLSCRDY parameter list. The length of the parameter list must be equal to the parameter list length EQU value defined by SRDY_PARMLN.

- **RETCODE=symbol**
  - **RETCODE=(r1-r12)**
    - (Required) - Specifies a 4-byte field to receive the return code on output. SCI return codes are defined in CSLSRR. Possible reason codes for CSLSCRDY are described in the following table.

- **RSNCODE=symbol**
  - **RSNCODE=(r1-r12)**
    - (Required) - Specifies the address of a 4-byte field to receive the CSLSCRDY reason code. SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCRDY are described in the following table.

- **SCITOKEN=symbol**
  - **SCITOKEN=(r1-r12)**
    - (Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

**CSLSCRDY return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLSCRDY macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>
</tr>
<tr>
<td>X'00002038'</td>
<td></td>
<td>The parameter list version is invalid.</td>
</tr>
<tr>
<td>X'01000010'</td>
<td>X'00004000'</td>
<td>SCI is not active.</td>
</tr>
<tr>
<td>X'00004FFF'</td>
<td></td>
<td>The function is not supported.</td>
</tr>
<tr>
<td>X'01000014'</td>
<td>X'00005000'</td>
<td>An SCI internal error occurred.</td>
</tr>
</tbody>
</table>

**Related reference:**

"CSLSCMSG: send message request" on page 228

**CSLSCREG: registration request**

The Structured Call Interface (SCI) registration request is used to create a connection between an IMSplex member and SCI. Before SCI can be used for
communication within the IMSplex, an IMSplex member must issue the CSLSCREG request and receive an SCI token when the request completes in order to be recognized by SCI.

This token is used with all subsequent SCI requests. If SCI terminates while the IMSplex member is active, the member is still registered when SCI becomes active again. The SCI token that the member received on the initial CSLSCREG request is still valid.

Restrictions:
- CSLSCREG is not supported when the caller's address space has been marked non-swappable by a SYSEVENT DONTSWAP call. Issuing a CSLSCREG in this environment produces unpredictable results. A caller that issued a SYSEVENT DONTSWAP must issue a SYSEVENT OKSWAP before registering with SCI.
- A single address space may register with SCI more than once. However, all registrations from a single address space must be made in the same PSW key and state (supervisor or problem) as the first active registration.

**CSLSCREG syntax**

**CSLSCREG DSECT syntax**

Use the DSECT function of a CSLSCREG request to include equate (EQU) statements in your program for the CSLSCREG parameter list length, the IMSplex types and the CSLSCREG return and reason codes.

```
►►CSLSCREG—FUNC=DSECT◄◄
```

**CSLSCREG REGISTER syntax**

The CSLSCREG FUNC=REGISTER request establishes a connection between an IMSplex member and SCI. An SCI token is returned on successful completion of this request. This token must be used on all subsequent SCI requests. Until the CSLSCRDY FUNC=READY request is issued, the IMSplex member receives only messages and requests that are routed directly to it (by SCITOKEN or by NAME). Messages and requests that are routed by TYPE are not routed to this member. Messages and requests routed by any method can be sent by this member when the CSLSCREG FUNC=REGISTER request has been successfully completed. The syntax for the REGISTER function of the CSLSCREG request follows.

```
►►CSLSCREG—FUNC=REGISTER—PARM=parm—IMSPLEX=imsplex—MBRNAME=membername◄◄
```
CSLSCREG parameters

**ABNDSTAT=NO**
- Indicates if SCI is to keep track of the member if the member abnormally terminates. If **ABNDSTAT=YES** is specified, SCI will retain an entry for the member with a status of ABTERM. If the member normally terminates or if the member abnormally terminates after a successful CSLSCDRG, SCI does not keep a record of the member.

This parameter is ignored for non-authorized IMSplex members.

**IMSPLEX=**<symbol>
- (Required) - Specifies the address of a 1- to 5-character IMSplex name. The IMSplex name identifies the SCI to which this request is directed. If specified as a symbol, the symbol references storage that contains the IMSplex name.

**INPUTEXIT=**<symbol>
- (Optional) - Specifies the address of the SCI input exit routine. The input exit is called each time there is a message or request for the member.
INPUTPARM=\texttt{symbol}

\textbf{(Optional)} - Specifies the address of an 8-byte area that contains member data. This data is passed to the input exit routine each time it is called. If specified as a symbol, the symbol references storage that contains the member data.

JOBNNAME=\texttt{symbol}

\textbf{(Optional)} - Specifies the address of an 8-byte area to receive the SCI jobname.

MBRNAME=\texttt{symbol}

\textbf{(Required)} - Specifies the address of an 8-byte name of the IMSplex member registering with SCI. For an authorized member, this name must be unique within the IMSplex. For a non-authorized member, this name does not need to be unique. If it is specified as a symbol, the symbol refers to storage that contains the IMSplex member name. Valid characters for the name are A-Z, 0-9, and special characters @, #, and $.

MBRVSN=\texttt{symbol}

\textbf{(Optional)} - Specifies the address of a 4-byte version of the IMSplex member registering with SCI. This version number is passed in the parameter list of the SCI Notify exit when this IMSplex member is the subject of the event. It is also passed in the parameter list of the SCI Input exit for messages and requests that originate from this member. If MBRVSN is not specified, the version number in the exit parameter list is set to zeros. If it is specified as a symbol, the symbol references storage that contains the IMSplex member version.

SCI does not validate this field; however, the field can be output on the QRY IMSPLEX command. It is assumed to have the following format: X'00vvrrmm'.

\begin{itemize}
  \item 00 - this byte is ignored
  \item vv - version number
  \item rr - release number
  \item mm - modification level or subrelease number
\end{itemize}

For example, X'00080100' would be output as 8.1.0.

NOTIFYEXIT=\texttt{symbol}

\textbf{(Optional)} - Specifies the address of the SCI Notify exit routine. The Notify exit is driven whenever there is a change of status of an IMSplex member.

NOTIFYPARM=\texttt{symbol}

\textbf{(Optional)} - Specifies the address of an 8-byte area that contains member data. This data is passed to the Notify exit routine each time it is called. If it is specified as a symbol, the symbol references storage that contains the member data.

PARM=\texttt{symbol}

\textbf{(Required)} - Specifies the address of a parameter list used by the request to pass the parameters to SCI. The length of the storage must be at least equal to the value of SREG_LN.

RETCODE=\texttt{symbol}

\textbf{(Required)} - Specifies the address of a 4-byte field to receive the CSLSCREG
return code. SCI return codes are defined in CSLSRR. Possible return codes for CSLSCREG are described in the following table.

**RETNAME**=symbol  
**RETNAME**=(r2-r12)  
(Optional) - Specifies the address of an 8-byte field to receive the name of the SCI that processes the registration request.

**RETTOKEN**=symbol  
**RETTOKEN**=(r2-r12)  
(Optional) - Specifies the address of a 16-byte field to receive the SCI token of the SCI that processes the registration request.

**RSNCODE**=symbol  
**RSNCODE**=(r2-r12)  
(Required) - Specifies the address of a 4-byte field to receive the CSLSCREG reason code. SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCREG are described in the following table.

**SCITOKEN**=symbol  
**SCITOKEN**=(r2-r12)  
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

**SCIVSN**=symbol  
**SCIVSN**=(r2-r12)  
(Optional) - Specifies the address of a 4-byte field to receive the SCI version number. The version number has the following format: 00vvrrmm.

- **00** This byte is reserved for future use. Currently, it is always 00.
- **vv** Version number.
- **rr** Release number.
- **mm** Modification level or subrelease number.

**Example:** SCI version 1.1.0 is shown as X'00010100'.

**SUBTYPE**=symbol  
**SUBTYPE**=(r2-r12)  
(Optional) - Specifies the address of the 8-byte subtype of the member registering with SCI. The subtype is defined by the user and can be any eight characters. If it is specified as a symbol, the symbol references storage that contains the subtype. If not specified, this parameter is set to blanks. If SUBTYPE is not specified, it will be set to blanks.

The subtype can contain alphanumeric characters (A-Z, 0-9), or printable characters (not case sensitive), with the exception of the characters &, <, and >. OM converts any invalid data placed in this field to periods (.) before sending the XML output to the client.

**TCB**=CURRENT  
**TCB**=JOBSTEP  
**TCB**=PARENT  
**TCB**=symbol  
**TCB**=(r2-r12)  
(Optional) - Specifies the TCB with which the new SCI connection is associated. The SCI connection persists until one of the following occurs:
- The member deregisters by using CSLSCDRG.
- The TCB associated with the connection terminates.
All callers of CSLSCREG can specify the following values for the TCB parameter:

**CURRENT**
Associates the SCI connection with the currently executing TCB. This is the default.

**JOBSTEP**
Associates the SCI connection with the JOBSTEP TCB of the TCB under which the CSLSCREG request is issued. This TCB is specified by TCBJSTCB.

**PARENT**
Associates the SCI connection with the TCB that attached the currently-executing TCB.

For non-authorized callers, the indicated TCB must have the same storage key associated with it as the caller's current PSW key (that is, TCBPKF must match the current PSW key).

Authorized callers can, in addition, identify an explicit TCB by specifying a symbol or register. If specified as a symbol, the symbol must be the label on a word of storage containing the address of the TCB. If specified as a register, the register must contain the TCB address.

**TYPE=membertypecode**
- **TYPE=’AOP’**
- **TYPE=’BATCH’**
- **TYPE=’CQS’**
- **TYPE=’DBRC’**
- **TYPE=’IMS’**
- **TYPE=’IMSCON’**
- **TYPE=’ODBM’**
- **TYPE=’OM’**
- **TYPE=’OTHER’**
- **TYPE=’RM’**
- **TYPE=’SCI’**

(Required) - Specifies the SCI member type of the address space that is registering with SCI.

If this parameter is passed as a literal, the literal must be enclosed in single quotation marks. If this parameter is passed as a symbol or register, the symbol or register must contain the member type code.

The code for the member type can be obtained by using the CSLSTPIX macro. Member types include:

- **AOP**  This SCI type is an automated operator program. It interacts with OM by sending commands and receiving responses to the commands.
- **Batch**  This SCI type is an IMS batch region. It interacts as an IMS DL/I batch or utility region.
- **CQS**  This SCI type is an IMS Common Queue Server. It provides access to a set of common queues within the IMSplex.
- **DBRC**  This SCI type is an IMS Database Recovery Control Region.
- **IMS**  This SCI type is an IMS region. It can include the database manager, transaction manager, and FDBR (an IMS control region that recovers
database resources when an IMS database manager fails). SUBTYPE is used to further qualify a particular control region (for example, DBDC, DBCTL, DCCTL, or FDBR).

**IMSCON**
This SCI type is a connector to IMS. It acts as an interface between IMS and protocols that are not supported by IMS directly (such as TCP/IP).

**ODBM**
This SCI type is an IMS Open Database Manager, which is part of the CSL. It receives requests to access and manipulate IMS databases from clients, such as IMS Connect or an ODBA application, and routes the requests to the IMS DB systems in the IMSplex that manage the database. When ODBM is used in support of IMS Connect and the IMS Universal drivers, ODBM translates the incoming database access requests from the low-level DRDA protocol into the DL/I calls used by IMS and back again on output.

**OM**
This SCI type is an IMS Operations Manager, which is part of the CSL. It receives commands from AOPs, routes the commands to other members of the IMSplex that have registered for the command, consolidates the responses to the command, and sends the output back to the originating AOP.

**Other**
This SCI type is any other address space that does not fall into one of the defined SCI types.

**RM**
This SCI type is an IMS Resource Manager, which is part of the CSL. It manages resources within the IMSplex and coordinates IMSplex-wide processes. SUBTYPE is used to further qualify whether there is a single RM in the IMSplex (SNGLRM) or there are multiple RMs in the IMSplex (MULTRM).

**SCI**
This SCI type is an IMS SCI, which is part of the CSL. It manages communications within the IMSplex.

### CSLSCREG return and reason codes

The following table lists the return and reason codes that can be returned on a CSLSCREG macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

**Table 67. CSLSCREG return and reason codes**

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'00000000'</td>
<td>X'00000000'</td>
<td>The request completed successfully.</td>

CSLSCRQR request return request

Issuing the CSLSCRQR request returns a request to the IMSplex member from which the request originated. The return request should be issued when the server has completed the request and is ready to return the output from the request.

CSLSCRQR returns a request to the IMSplex member from which the request originated. It should be issued when the server has completed the request and is ready to return the output from the request. It copies the output back to the requestor’s address space.

Only request servers can issue CSLSCRQR because an IMSplex member cannot issue the macro without first receiving a request. A request server must be authorized and running key 7.

CSLSCRQR syntax

CSLSCRQR DSECT syntax

Use the DSECT function of a CSLSCRQR request to include equate (EQU) statements in your program for the CSLSCRQR parameter list length and the CSLSCRQR return and reason codes.

```
►►CSLSCRQR—FUNC=DSECT
```

CSLSCRQR RETURN syntax

The syntax for the CSLSCRQR FUNC=RETURN request follows.

```
►►CSLSCRQR—FUNC=RETURN—SCITOKEN=scitoken—PARM=parm—NOCPYABN=N
NOCPYABN=Y

►►REQUESTTOKEN=REQUESTTOKEN=RQSTRC=REQUESTRETURNCODE

►►RQSTRSN=REQUESTREASONCODE=RETURNCODE—RSNCODE=REASONCODE
```

CSLSCRQR parameters

```
PARM=symbol
PARM=(r1–r12)
```

(Required) - Specifies the CSLSCRQR parameter list. The length of the parameter list must be at least equal to the basic parameter list length of SRQR_PARMLEN. However, if you code certain parameters on CSLSCRQR, you must provide a longer parameter list. Use the following table to decide if you must provide a parameter list of a longer length. If you are using more than one parameter listed, and the parameters have different minimum length values, always use the one that ends with the largest numeric value.
You can also define your parameter list to have a length of SRQR_PRMLMX bytes. This EQU is set to the length of the longest CSLSCRQR parameter list version, and the parameter list will always be long enough for any combination of macro parameters. However, this maximum length might change because of maintenance or across IMS releases.

**NOCPYABN=N | Y**  
(Optional) - Specifies how SCI should handle an abend during the copy phase of the request return process.

- **N**  
  SCI will take a dump and issue a message as determined by the logic in the ARR or FRR. NOCPYABDN=N is the default.

- **Y**  
  SCI will not take a dump or issue a message if an abend is encountered while it attempts to copy data back to the requestor. SCI will only write an entry to the LOGREC data set.

This parameter was added as part of the Version 2 parameter list. If you include this parameter, your parameter list must be at least equal to the value specified by SQRQ_PRMLV2.

**RQSTRC=**  
**RQSTRC=(r1-r12)**  
(Optional) - Specifies the return code that is associated with the request being returned. This return code will be given to the requesting member in the storage pointed to by the RETCODE parameter of the CSLSCRQS that originated this request. If this parameter is not specified, a return code of zero will be given to the requesting member.

If specified as a symbol, the symbol references storage that contains the return code.

**RQSTRSN=**  
**RQSTRSN=(r1-r12)**  
(Optional) - Specifies the reason code that is associated with the request being returned. This reason code will be given to the requesting member in the storage pointed to by the RSNCODE parameter of the CSLSCRQS that originated this request. If this parameter is not specified, a reason code of zero will be given to the requesting member.

If specified as a symbol, the symbol references storage that contains the return code.

**RQSTTKN=**  
**RQSTTKN=(r1-r12)**  
(Required) - Specifies the request token that is associated with the request being returned. This request token can be obtained from the input exit parameter list (INXP_RQSTTKN) when the request was presented to the request processing member.

If specified as a symbol, the symbol references storage that contains the return code.

**RETCODE=**  
**RETCODE=(r1-r12)**  
(Required) - Specifies the address of a 4-byte field to receive the CSLSCRQR
return code. SCI return codes are defined in CSLSRR. Possible return codes for CSLSCRQR are described in the following table.

<table>
<thead>
<tr>
<th>Return code</th>
<th>Reason code</th>

<tr>
<td>X'00005504'</td>
<td></td>
<td>An abend occurred when the member parameters were copied to the target address space.</td>
</tr>
<tr>
<td>X'00005508'</td>
<td></td>
<td>An abend occurred when the member parameters were copied to the target address space, but the dump and message were suppressed because NOCPYABN=Y was specified.</td>
</tr>
</tbody>
</table>
CSLSCRQS: send request

By issuing the CSLSCRQS request, an IMSplex member can send a request to another member in the IMSplex. The target member can be specified by SCITOKEN, member name, or member type.

A request in an IMSplex can contain both input and output data (from the target member's perspective). This contrasts to a message that can only contain input data (again, from the target member's perspective). The data of a request is copied to the target member's address space. The function is processed, and the output is returned to the requestor's address space. If the request included an ECB, control is returned to the requesting module after the request has been processed by SCI. The requestor must then wait on the ECB.

The ECB is posted when the request processing has completed. The requestor then looks at the RETCODE and RSNCODE fields to determine the outcome of the request. If no ECB is included in the request, the RETCODE and RSNCODE fields can be used to determine the outcome of the request when the requesting module gets control back from SCI.

Note: Before issuing CSLSCRQS, the requester should clear the fields that will receive the address and length of the SCI Allocated Output parameters. If the request is not sent to the destination because of an error, or if there is no data to output, SCI will not update the length and address fields.

CSLSCRQS syntax

DSECT syntax

Use the DSECT function of a CSLSCRQS request to include equate (EQU) statements in your program for the CSLSCRQS parameter list length, the IMSplex types and the CSLSCRQS return and reason codes.

SEND REQUEST syntax

The syntax for the CSLSCRQS FUNC=SEND request follows.

CSLSCRQS—FUNC=SEND—SCITOKEN=scitokenaddress—PARM=parmaddress

MBRPARM=mbrparmlistaddress—MBRPCNT=mbrparmcnt—MBRFUNC=mbrfunctioncode

MBRSFUNC=mbrsubfunctioncode—FUNCTYPE=DEST—FUNCTYPE=SENDER—ECB=ecbaddress—TOKEN=tokenaddress—RETCODE=returncodeaddress—RSNCODE=reasoncodeaddress

- TYPE='RM'
- TYPE='SCI'

SUBTYPE=subtypeaddress

CSLSCRQS parameters

ECB=symbol
ECB=(r1-r12)
(Optional) - Specifies the address of a z/OS ECB used for asynchronous requests. When the request is complete, the ECB specified is posted. If an ECB is not specified, the task is suspended until the request is complete. If an ECB is specified, the invoker of the macro must issue a WAIT (or equivalent) after receiving control from CSLSCRQS, before using or examining any data returned by this macro (including the RETCODE and RSNCODE fields).

FUNCTYPE=DEST
FUNCTYPE=SENDER
(Optional) - Specifies that the MBRFUNC and MBRSFUNC are defined by the DEST (destination) of this request or the SENDER of the request. This indicator is passed to the recipient of the request in the SCI Input exit parameter list.

MBRFUNC= symbol
MBRFUNC= (r1-r12)
(Required) - Specifies a 4-byte member function code that is passed to the destination of the request in the SCI Input exit parameter list. This function code, along with the MBRSFUNC, identifies the request that is being sent.

If MBRFUNC is a symbol, the symbol points to a four-byte area of storage that contains the function code.

MBRPARM= symbol
MBRPARM= (r1-r12)
(Required) - Specifies the address of a pre-built parameter list. This parameter list must be built by the requesting module and consists of sets of triplets. Each triplet describes a single parameter in the member parameter list and consists of:

parameterlength
Four-byte parameter that specifies the length of the member parameter.

parameteraddress
Four-byte parameter that specifies the address of the member parameter.
**datatype**

Four-byte parameter that specifies how this parameter is to be handled by SCI. Equates are provided for each type (included with CSLSCODE). These equates can be used to set the value of data type. Possible values are:

- **IN** The parameter is an input parameter. It is copied to the destination address space with the request.
- **OUT** The parameter is an output parameter. It is copied back to the requesting address space when the request is completed by the server. The storage for the parameter must be allocated before the request is issued.
- **IO** The parameter is both an input and an output parameter. It is copied to the target address space with the request and it is copied back to the requesting address space when the request is complete.
- **SCI** The parameter is an SCI allocated output parameter. The storage for the parameter is allocated in the requestor’s address space when the request is complete. The address of the storage will be returned in the parameter address field and the length will be returned in the parameter length field. The storage must be released by the requestor using the CSLSCBFR request. The eight bytes immediately in front of the address returned for an SCI-allocated output parameter are available for use by the requestor. These eight bytes are not cleared, and might contain residual data from a prior use of the buffer.

The two methods for passing parameters in a parameter list are *by address* and *by value*. Both of these methods can be used when passing parameters in a CSLSCCRQS request. The triplet must be setup so that SCI will handle the parameter properly.

- **By address**
  
  To pass a parameter by address, the address of the parameter must be passed in `parameteraddress` and the length of the parameter must be passed in `parameterlength`. SCI will get the parameter from `parameteraddress` for data type IN and IO and will store the parameter at `parameteraddress` for data type OUT and IO. The address at which the parameter is stored and its length is returned for data type SCI.

- **By value**
  
  To pass a parameter by value, the parameter must be passed in `parameteraddress` and zero must be passed in `parameterlength`. When the length is zero, SCI will copy the value contained in `parameteraddress` to the destination for data type IN. All other data types must be passed by address since SCI requires an address to store any output parameters.

**Member Parameter List**: The user parameters specified here are presented to the program that receives the request in the member parameter list, the address of which is contained in the Input Exit Parm area field INXP_MBRPLPTR. Each parameter is represented by eight bytes, the first four bytes contain `parameterlength` and the second four bytes contain `parameteraddress` (if `parameteraddress` is an address, the second four bytes point to storage in the local address space, not the requesting address space). If the parameter’s data type is SCI, the first four bytes will contain a length of four and the second word’s value is unpredictable.
Null Parameters: In some cases a request processing module expects a set number of parameters with a defined order. If a request is to be sent that does not contain all the parameters, null parameters must be sent to ensure the data buffer contains everything that is expected. Null parameters can be sent by specifying zero for parameterlength and parameteraddress. The eight bytes that represent the parameter in the data buffer will contain zeros. This is true for any data type (IN, OUT, IO or SCI) or method of passing parameters (by address or by value).

MBRPCNT=symbol
MBRPCNT=(r1-r12)
(Required) - Specifies a 4-byte field that contains the number of member parameters that are included in MBRPARM.

MBRSFUNC=symbol
MBRSFUNC=(r1-r12)=
(Optional) - Specifies a 4-byte member subfunction code that is passed to the destination of the request in the SCI input exit parameter list. This subfunction code, along with the MBRFUNC, identifies the request that is being sent.

If MBRSFUNC is a symbol, the symbol points to a 4-byte area of storage that contains the sub-function code.

NAME=symbol
NAME=(r1-r12)
(Optional) - Specifies the address of an 8-byte member name of the destination of this request. This name can be obtained from the Notify exit (when the member joins the IMSplex) or by issuing a CSLSCQRY request.

Note: One of the routing parameters (NAME, TOKEN or TYPE) must be included.

PARM=symbol
PARM=(r1-r12)
(Required) - Specifies the address of a parameter list used by the request to pass the parameters to SCI. The length of the storage must be at least equal to the value of SRQS_LN.

RETCODE=symbol
RETCODE=(r1-r12)
(Required) - Specifies the address of a 4-byte field to receive the CSLSCRQS return code. SCI return codes are defined in CSLSRR. Possible return codes for CSLSCRQS are described in the following table.

RETNAME=symbol
RETNAME=(r1-r12)
(Optional) - Specifies the address of an 8-byte field to receive the name of the SCI that processes the request.

RETTOKEN=symbol
RETTOKEN=(r1-r12)
(Optional) - Specifies the address of a 16-byte field to receive the SCI token of the SCI that processes the request.

RSNCODE=symbol
RSNCODE=(r1-r12)
(Required) - Specifies the address of a 4-byte field to receive the CSLSCRQS reason code. SCI reason codes are defined in CSLSRR. Possible reason codes for CSLSCRQS are described in the following table.

SCITOKEN=symbol
**SCITOKEN=**(r1-r12)
(Required) - Specifies a 16-byte field containing the SCI token. This token uniquely identifies this connection to SCI. The SCI token was returned by a successful CSLSCREG FUNC=REGISTER request.

**TOKEN=**symbol
**TOKEN=**(r1-r12)
(Optional) - Specifies the address of the 16-byte SCI token of the destination of this request. This token can be obtained either from the Notify exit (when the member joins the IMSplex) or by issuing a SLSCQRY message.

*Note:* One of the routing parameters (NAME, TOKEN, TYPE) must be included.

**TYPE=**symbol
**TYPE=**(r1-r12)
**TYPE=**'AOP'
**TYPE=**'BATCH'
**TYPE=**'CQS'
**TYPE=**'DBRC'
**TYPE=**'IMS'
**TYPE=**'IMSCON'
**TYPE=**'ODBM'
**TYPE=**'OM'
**TYPE=**'OTHER'
**TYPE=**'RM'
**TYPE=**'SCI'

Input parameter that specifies the IMSplex member type of the IMSplex member to which this request should be routed. The IMSplex member type routing can be further qualified by using the SUBTYPE parameter. If TYPE is specified, SCI chooses the IMSplex member of the requested type to which the request is sent.

If member type is specified as a literal, the literal must be enclosed in single quotes. If this parameter is passed as a symbol or register, the symbol or register must contain the member type code. The member type code can be obtained by using the CSLSTPIX macro.

*Note:* One of the routing parameters (NAME, TOKEN, TYPE) must be included.

**CSLSCRQS return and reason codes**

The following table lists the return and reason codes that can be returned on a CSLSCRQS macro request. Also included is the meaning of a reason code (that is, what possibly caused it).

*Table 70. CSLSCRQS return and reason codes*

<table>

Chapter 9. CSL Operations Manager XML output

Command responses that are returned through the OM API are embedded in XML tags using codepage 037. XML output is generated for responses to the CSLOMI, CSLOMCMCMD, and CSLOMQRY requests.

**Note:** The OM response is intended as a programming interface, not as an interface that produces prebuilt messages to be displayed on a screen. For OM requests, the output is passed back in the OUTPUT= buffer. For messages, the output is returned to the SCI input exit. The OM response is returned encapsulated in XML tags.

**Related concepts:**

- “CSL OM automated operator program clients” on page 139

CSLOMI XML output examples

Each of the command syntax examples contain a sample of CSLOMI XML output. The examples present different scenarios that generate XML output based on the commands that are used in the example.

CSLOMI XML output

One or more of the sets of tags in the following output example is returned on each CSLOMI request.

```
<imsout>
  <ctl>
    <omname> </omname>
    <omvsn> </omvsn>
    <xmlvsn> </xmlvsn>
    <statime> </statime>
    <stotime> </stotime>
    <staseq> </staseq>
    <stoseq> </stoseq>
    <rqsttkn1> </rqsttkn1>
    <rqsttkn2> </rqsttkn2>
    <rc> </rc>
    <rsn> </rsn>
    <rsnmsg> </rsnmsg>
  </ctl>
  <cmdclients>
    <mbr name="membername"> </mbr> </cmdclients>
  <cmdsyntax> </cmdsyntax>
  <cmdtd> </cmdtd>
  <cmdtext> </cmdtext>
```
Issue IMS command example

The following examples are CSLOMI XML output. In the following command example, the QUERY TRAN command was routed to IMSA with a timeout value of 10 seconds.

OM API Input:
CMD(QUERY TRAN) NAME(SKS*) ROUTE(IMSA) TIMEOUT(10) RQSTTKN2(QTRANCMD)

OM API Output:
<imsout>
<ctl>
<omname>OM1</omname>
<omvsn>1.1.0</omvsn>
<xmlvsn>1</xmlvsn>
<statime>1999.341 12:52:44.46</statime>
<stotime>1999.341 12:52:44.46</stotime>
<staseq>B342BCC72A34D206</staseq>
<stoseq>B342BCC75CD52208</stoseq>
<rqsttkn2>QTRANCMD</rqsttkn2>
<rc>0</rc> <rsn>0</rsn>
</ctl>
<cmd>
<master>IMS1</master>
<verb>QRY</verb>
<kwd>TRAN</kwd>
<input>QUERY TRAN</input>
</cmd>
Query client list example

In the following client list example, the Operations Manager (OM) returns a list of client names that are currently registered for command processing.

OM API Input:
QUERY(CMDCLIENTS) RQSTTKN2(CLIENTLIST)
OM API Output:

Query command syntax example

The following command syntax example returns the command syntax for currently registered commands. In this example, the QUERY TRAN command is the only command that is registered to OM, and the keyword NAME is associated with it.

OM API Input:
QUERY(CMDSYNTAX) RQSTTKN2(CMDLIST)
OM API Output:

CSLOMCMD output

The command syntax example contains a sample of CSLOMCMD XML output. The example presents a scenario that generates XML output based on the commands that are used in the example.

CSLOMCMD XML output

The tags in the following output example can be returned as a result of a CSLOMCMD request.

```xml
<?xml version="1.0"?>
<!DOCTYPE imsout SYSTEM "imsout.dtd">
<imsout>
  <ctl>
    <omname> </omname>
    <omvsn> </omvsn>
    <xmlvsn> </xmlvsn>
    <statime> </statime>
    <stotime> </stotime>
    <staseq> </staseq>
    <stosq> </stosq>
    <rqsttkn1> </rqsttkn1>
    <rc> </rc>
    <rsn> </rsn>
  </ctl>
  <cmderr>
    <mbr name="membername">
```

“XML tags returned as CSL OM responses” on page 263

QUERY TRAN command (Commands)

CSLOMCMD output

The command syntax example contains a sample of CSLOMCMD XML output. The example presents a scenario that generates XML output based on the commands that are used in the example.

CSLOMCMD XML output

The tags in the following output example can be returned as a result of a CSLOMCMD request.

```xml
<?xml version="1.0"?>
<!DOCTYPE imsout SYSTEM "imsout.dtd">
<imsout>
  <ctl>
    <omname> </omname>
    <omvsn> </omvsn>
    <xmlvsn> </xmlvsn>
    <statime> </statime>
    <stotime> </stotime>
    <staseq> </staseq>
    <stosq> </stosq>
    <rqsttkn1> </rqsttkn1>
    <rc> </rc>
    <rsn> </rsn>
  </ctl>
  <cmderr>
    <mbr name="membername">
```
CSLOMQRY output

Each of the command syntax examples contain a sample of CSLOMQRY XML output. The examples present different scenarios that generate XML output based on the commands that are used in the example.

CSLOMQRY XML output

The tags in the following output example can be returned as a result of a CSLOMQRY request.

The command syntax and translatable text that is returned as a result of the CSLOMQRY QUERY TYPE(CMDSYNTAX) request includes information for type-2 commands.

<imsout>
  <ctl>
    <omname> </omname>
    <omvsn> </omvsn>
    <xmlvsn> </xmlvsn>
    <statime> </statime>
    <stotime> </stotime>
    <staseq> </staseq>
    <stoseq> </stoseq>
    <rqsttknl> </rqsttknl>
    <rc> </rc>
    <rsn> </rsn>
  </ctl>
</imsout>
CSLOMOUT output

The command syntax example contains a sample of CSLOMOUT XML output. The example presents a scenario that generates XML output based on the commands that are used in the example.

Unsolicited output message encapsulated in XML tags

The tags in the following output example can be returned as a result of a CSLOMOUT request.

```xml
<imsout>
  <ctl>
    <omname></omname>
    <omvsn></omvsn>
    <xmlvsn></xmlvsn>
    <statime></statime>
    <staseq></staseq>
    <uom>UOM</uom>
  </ctl>
  <msgdata>
    <mbr name="membername">
      <typ></typ>
      <styp></styp>
      <msg></msg>
    </mbr>
  </msgdata>
</imsout>
```

XML tags returned as CSL OM responses

Different XML tags can be returned as CSL OM responses. Each tag name is delimited by the characters < and >. Tags can be nested within parent tags to encapsulate related information.

Data or other sets of tags are contained between these start and end tags. In the list of tags, indentation indicates that the tags are nested within the parent tags.

```xml
<?xml version "1.0"?>
The version of XML used in this output.
<!DOCTYPE imsout SYSTEM "imsout.dtd">
The DOCTYPE tag identifies the file that contains the document type definition (DTD). The DTD describes the structure that is supported for this type of XML document. Users of z/OS can find the DTD information in the CSLOMDTD member, located in the IMS.SDFSRESL data set.

<imsout> </imsout>
The <imsout> </imsout> tags encapsulate the output from OM. These tags are returned on every request.

<ctl> </ctl>
The <ctl> </ctl> tags encapsulate the control information that is returned by OM. These tags are returned on every request and include the following control information:

```xml
<omname>om name</omname>
Indicates the name of the OM that processed this request. The name is specified on the OMNAME= execution parameter of the CSLOIxxx PROCLIB member.
```
<omvsn>om version number</omvsn>
Indicates the OM version number.

<xmlvsn>xml version number</xmlvsn>
Indicates the XML version number.

<statime>starttime</statime>
Indicates the time that OM started processing the request. The field is in the following format: yyyy.ddd hh:mm:ss.th

<stotime>stoptime</stotime>
Indicates the time that OM completed request processing. The field is in the following format: yyyy.ddd hh:mm:ss.th

<staseq>startsequence</staseq>
Indicates the sequence value when OM started processing the request. This value can be used for sorting and is in printable EBCDIC hexadecimal format.

<stoseq>stopsequence</stoseq>
Indicates the sequence value when OM stopped processing the request. This value can be used for sorting and is in printable EBCDIC hexadecimal format.

<rqsttkn1>requesttoken1</rqsttkn1>
Indicates the user-specified RQSTTKN1 value that is associated with the response. OM converts unprintable characters to periods (.) in the output.

<rqsttkn2>requesttoken2</rqsttkn2>
Indicates the user-specified RQSTTKN2 value that is associated with the response. OM converts unprintable characters to periods (.) in the output.

<rc>returncode</rc>
The return code for the request in printable EBCDIC hexadecimal format.

<rsn>reasoncode</rsn>
The reason code for the request in printable EBCDIC hexadecimal format.

<uom>unsolicited output message</uom>
Indicates that the XML is for an unsolicited output message

<cmdclients> </cmdclients>
Encapsulates information about OM clients. These tags can be returned on a QUERY(CMDCLIENTS) request.

<mbr name="membername"></mbr>
Indicates the name of the IMSplex member that is registered for commands.

<typ>membertype</typ>
Indicates the type of IMSplex member.

<styp>membersubtype</styp>
Indicates the IMSplex member subtype. OM converts unprintable characters to periods (.) in the output.

<vsn>memberversion</vsn>
Indicates the member version number.
<jobname>memberjobname</jobname>
Indicates the member job name.

<cmdtd> </cmdtd>
Encapsulates the Document Type Definition (DTD) that are defined by OM
for command syntax and OM output XML. These tags can be returned on
a QUERY(CMDSYNTAX) request.

<cmdsyntax> </cmdsyntax>
Encapsulates the XML definitions for the commands that are registered to
OM from all of its clients. These tags can be returned on a
QUERY(CMDSYNTAX) request.

<cmdtext> </cmdtext>
Encapsulates the translatable text strings that are associated with the XML
command syntax tags. These tags can be returned on a
QUERY(CMDSYNTAX) request.

<cmd> </cmd>
Encapsulates the command information that was passed to OM. These tags
can be returned on a command request. The output returned in these tags
is what was provided on the CMD= parameter on the CSLOMBLD macro.
The following tags are included within the <cmd> tags:

(master> </master>
Encapsulates the name of the command processing client that was
tagged as the master when sending the command. This
information will not be present unless the command was
successfully sent to at least one command processing client.

<userid> </userid>
Encapsulates the user ID of the originator of the command.

<verb> </verb>
Encapsulates the short form of the command verb that was
processed by OM. The verb might have been passed to OM in a
long form.

<kwd> </kwd>
Encapsulates the command keyword that was processed by OM.

<input> </input>
Encapsulates the actual input command string that was passed to
OM. The following characters are converted to periods (.) to
maintain the validity of the output XML:
• Greater than signs (>)
• Less than signs (<)
• Ampersands (&)
• Non-printable characters

<cmdrsphdr> </cmdrsphdr>
Encapsulates the command header information that describes the data
fields returned in the command response. These tags can be returned on a
command request.

<hdr .../>
Defines the attributes of columns of data fields.
The command response header information is in the format shown
in the following format example:

<hdr slbl="ss" llbl="llll" scope="c" sort="d" key="e" scroll="f" len="g" dtype="h" align="i" skipb="no"/>
slbl  Short label used to match data description with data value
      that is returned by the `<cmdrspdata>` tag.
      
The short label values vary by command. Refer to the
documentation for each command to determine what
values can be returned for a specific command.

llbl  Long label that can be used as the table column header.
      
The long label values vary by command. Refer to the
documentation for each command to determine what
values can be returned for a specific command.

scope Indicates if the data is global or local.
      
GBL   Indicates that the data is global. For query output,
global data applies to all resources of the same
name, but is returned only once in the command
response for a specific resource name. Global
information applies to other rows of the same
resource name for different IMSplex member
names. The resource name is the data field
identified by a KEY="1" attribute. If an application
chooses to transform the command response data
into a table to be displayed for a user, the global
data value can be propagated to other rows for the
same resource name.

LCL   Indicates that the data is local. For query output,
local data applies only to a specific resource name
in a specific IMS. Different IMS systems can return
different values for local data fields. Each IMS
returns its local value when it is available. If an
application chooses to transform the command
response data into a table to be displayed for a
user, the local data value should not be propagated
to other rows for the same resource name.

sort Indicates whether or not this field should be sorted or the
sort direction.
      
A     Sort in ascending order.

D     Sort in descending order.

N     Do not sort field.

key Indicates the sort priority for this field.
      
0     Field is not sorted.

1     The highest priority sort field.

2     The second highest priority sort field.

n     The n the priority sort field.
      
The priority value indicated on KEY= in the `<cmdrspdhdr>`
tag has been predetermined. Some command responses can
specify multiple sort fields. Several fields are listed within
the `<cmdrspdhdr>` tags with their sort priorities:
* Trancode - 1
* MbrName - 4
* CC - 0
The following code example causes the command results to be sorted with the following priority:
1. Trancode
2. Qcnt
3. LQcnt
4. MbrName

<?xml version="1.0"?>
<!DOCTYPE imsout SYSTEM "imsout.dtd">
<imsout>

</tbody>
</table>

Depending on which fields were selected using the SHOW parameter of the QUERY command, not all intermediate priority value fields will be displayed. That is, the results could display fields whose priority values were set at 1 and 4, but not display fields whose priority values were set at 2 and 3. A program might leave the records in the original order, sort them using the predetermined priority values, or sort by other fields using criteria set locally by the user.

scroll Indicates whether this field is scrolled off of the screen when TSO SPOC shifts the screen to the right.

NO Do not scroll the field.

YES Allow the field to scroll off the screen.

len Maximum length of data (data returned could contain fewer characters). If a table of data is being created from the output response, this value can be used to determine the width of the column that is displayed for this attribute. If the value for this field is “”, this is a variable length field.

dtype Describes the original data type. All data is returned in character format. However, some fields represent numeric data. Data that originated as integer might need to be converted from character to integer in order to perform mathematical calculations.

CHAR The output field represents character data.

INT The output field is the character representation of integer data.

align Indicates recommended column alignment if data is to be formatted into columns.

RIGHT Data is right-aligned, for example, numeric data.

CENTER Data is centered.

LEFT Data is left-aligned, for example, character data.

skipb no The column is displayed on the TSO SPOC output,
even if no client returned any information for this column. This is the default.

yes The column is not displayed on the TSO SPOC output if no client returned any information for this column.

<dyn attr="cmdrspdata"/>

Encapsulates the command response detail information. These tags can be returned on a command request. The tags contain the actual data that is described by the <cmdrsphdr> </cmdrsphdr> tags.

Refer to the documentation for each command to determine what values can be returned for a specific command.

<cmdrspdata>

Contains a logical line of command response output for a particular resource. The response data contains various tags in the form name(value). The name maps to short label (slbl=) values in the <hdr> tag. This is shown in the following example, with the values TRAN and PSB.

<cmdrsphdr>
<hdr slbl="TRAN" llbl="Trancode" ...
<hdr slbl="PSB" llbl="PSBname" ...
</cmdrsphdr>
<cmdrspdata>
<rsp>TRAN(A ) PSB(A11 ) </rsp>
<rsp>TRAN(B ) PSB(B22 ) </rsp>
<rsp>TRAN(C ) PSB(C33 ) </rsp>
</cmdrspdata>

The <hdr> tag includes a long label value (llbl=), which can be used as column headings. This is shown in the following output example, specifically Trancode and PSBname.

<table>
<thead>
<tr>
<th>Trancode</th>
<th>PSBname</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A11</td>
</tr>
<tr>
<td>B</td>
<td>B22</td>
</tr>
<tr>
<td>C</td>
<td>C33</td>
</tr>
</tbody>
</table>

The values included in the response data propagate the data columns of the SPOC output. Other tags in the <hdr> tag describe formatting attributes for values in that column.

<msgdata>

Encapsulates pre-built IMS messages. The messages can be of any type including informational, warning, or error messages. These tags can be returned on a command request.

<msg>

Contains a logical command response output for a resource in a message format. The message starts with a message number (for example, DFSnnnnnI). There is no LL field or X’15’ new line character.

<cmderr>

Encapsulates the return and reason code information returned by OM or a command processing client. These tags are returned on command requests.
when an error specific to a command processing client must be returned. For each IMSplex member with an error, the following information is returned.

<mbr name="membername"></mbr>
Indicates the name of the IMSplex member for which an error was detected.

<typ>membertype</typ>
Indicates the type of IMSplex member.

<styp>membersubtype</styp>
Indicates the IMSplex member subtype. OM converts unprintable characters to periods (.) in the output.

<rc>returncode</rc>
Indicates the return code for the IMSplex member in printable EBCDIC hexadecimal format.

<rsn>reasoncode</rsn>
Indicates the reason code for the IMSplex member in printable EBCDIC hexadecimal format.

<cmdsecerr> </cmdsecerr>
Encapsulates the return and reason code information returned by the OM security exit, SAF and RACF, or equivalent. If the OM security exit rejected the command for any reason, the user data from the security exit is also encapsulated here.

<exit> </exit>
Encapsulates the return code and user data from the OM security exit.

<rc>returncode</rc>
Indicates the return code from the OM security exit in printable EBCDIC hexadecimal format.

<userdata>userdata</userdata>
Indicates the user data returned from the OM security exit in the OSCX_USERDATA field of the OM Command Security user exit parameter list (CSLOSCX). OM converts unprintable characters to periods (.) in the output.

<saf> </saf>
Encapsulates the return and reason codes from the SAF and RACF or an equivalent.

<rc>returncode</rc>
Indicates the return code from the SAF in printable EBCDIC hexadecimal format.

<racfcrc>racfreturncode</racfcrc>
Indicates the return code from RACF or equivalent security product in printable EBCDIC hexadecimal format.

<racfrsn>racfreasoncode</racfrsn>
Indicates the reason code from RACF or equivalent security product in printable EBCDIC hexadecimal format.

Chapter 10. REXX SPOC API and the CSL

The REXX SPOC API allows REXX programs to submit commands to OM and to retrieve the command responses.

REXX SPOC API environment with the CSL OM

The REXX SPOC API allows REXX programs to set up the IMSplex environment, submit commands to OM, and to retrieve the command responses.

There are three phases related to using the REXX SPOC API with the CSL OM:
1. Set up the REXX environment
2. Set up the IMSplex environment and issue commands
3. Retrieve the command responses

Setting up the REXX environment in a CSL

By issuing the ADDRESS command, you can call the program CSLULXSB to set up the REXX environment. This program establishes the REXX subcommand environment for the REXX SPOC API.

►►ADDRESS—LINK—'CSLULXSB'◄◄

Note: Other forms of the ADDRESS command might not work in the Tivoli® NetView® for z/OS environment.

Setting up the IMSplex environment

By switching the default host command to IMSSPOC and issuing the ADDRESS command, you can set up the IMSplex environment. After you set the default host command to IMSSPOC, IMSSPOC executes subsequent host commands issued by the REXX program that is running.

►►ADDRESS—IMSSPOC◄◄

After you set the default host command to IMSSPOC, IMSSPOC executes subsequent host commands issued by the REXX program that is running. You can switch to other host commands by using the ADDRESS command with other hosts. For example:

ADDRESS TSO
ADDRESS MVS
ADDRESS ISPEXEC

You can then issue commands that are specific to those environments.

Note: If you issue commands other than the subcommands described here in the REXX environment, they are sent to OM for processing.
IMS subcommand

The IMS subcommand establishes the name of the IMSplex. You must issue the IMS subcommand to establish the IMSplex name before any other commands can be issued. A prefix of “CSL” is automatically added to the name that you specify.

```
IMSPLEX_NAME
```

ROUTE subcommand

Use the ROUTE subcommand to set the name of the command processors. The command processors are the specific systems that will execute subsequent IMS commands. If you do not specify a command processor:

- the previous routing value is removed
- commands are routed to all members of the IMSplex. This is the default.

If “*” is specified, the command is routed to all registered command processing clients in the IMSplex. If “%” is specified, the command is routed to only one command processing client in the IMSplex that is registered for the command and that has MASTER capability. The Operations Manager chooses the command processing client.

The ROUTE subcommand is optional.

```
ROUTE command_processor
```

CART subcommand

Use the Command and Response Token (CART) subcommand to set the name of the command and response token. This 16-character text string token is used to retrieve the command response.

You must issue the CART subcommand before you can issue any IMS commands.

```
CART token_name
```

WAIT subcommand

Use the WAIT subcommand to provide a timeout value to OM. The time value must be in the form MMM:SS or ssss. The maximum value you can specify is 999:59. The WAIT subcommand is optional.

```
WAIT time_value
```
Issuing type-2 IMS commands

You issue IMS commands, including type-2 commands, by including them in the REXX program stream as quoted strings or as REXX variables that resolve to quoted strings.

Examples of type-2 commands

"QUERY IMSPLEX SHOW(ALL)"
"DIS ACT"
\texttt{tranlist} = "PETER1,MATT1"
"QUERY TRAN NAME("tranlist")"

CSLULGTS: retrieving command responses in XML

By issuing the CSLULGTS request, you can retrieve command responses. The CSLULGTS command puts the command responses to a stem variable so that REXX can access them.

\texttt{CSLULGTS(stem\_name,token\_name,\"wait\_time\")}

\textbf{stem\_name}

After the CSLULGTS command completes successfully, the stem variable contains XML statements. Each row of the stem variable contains one XML statement. If the beginning and ending XML tags are adjacent (that is, no other XML tags exist between them), they are placed in the same row of the stem variable. A single row of a stem variable might look like this:

\texttt{<rsp>TRAN(VIDB  ) MBR (IMS2  ) CC( 0) </rsp>}

\textbf{token\_name}

The name of the command and response token (CART). It should match the name specified on the CART subcommand.

\textbf{wait\_time}

A timeout value for the CSLULGTS command. The CSLULGTS command waits until the command completes, but the wait lasts only as long as the time specified. The wait time is in the format MMM:SS or ssss. The maximum timeout value is 999:59. Enclose this value in quotes.

\textbf{Note:} This timeout value is not the same as the timeout value for the WAIT subcommand; however, this \texttt{wait\_time} should be at least as long as the value specified on the WAIT subcommand. Otherwise, no command response are received for long running commands.

If no response is received the first time, you can issue the CSLULGTS command again.

CSLULOPT: including format identifiers in command responses

By issuing the CSLULOPT request, you can specify whether a command response should contain format IDs. Automated operator programs (AOPs) use format identifiers (FID) to identify the record format of specific lines of a command response.

Invoke CSLULOPT before you issue the IMS operator command. The setting you select on CSLULOPT is in effect for this REXX program until you explicitly change it.
FID
MYVAR=CSLULOPT(
FID
NOFID
'LRECL=number'
'WRAP'
'F=BYCOL'
'BYRSC'
)

F Specifies an output option. The possible options are:

BYCOL
Group lines by column.

BYRSC
Group lines by resource.

WRAP
Wrap individual lines (default).

FID
Specifies that the command response includes the FID. The default is FID.

LRECL
Specifies the logical record length as a numeric value.

NOFID
Specifies that the command response does not include the FID.

MYVAR
A variable that you can specify that contains the return code.

Related reference:

CSLULGTP: retrieving command responses directly to a REXX stem variable

By issuing the CSLULGTP request, you can retrieve command responses from OM and put the command response into a REXX stem variable. The REXX program then refers to the information in the stem variable directly, rather than parsing XML statements, as it does with the CSLULGTS request.

CSLULGTP—(stem_name,—token_name,—"wait_time")

stem_name
After the CSLULGTP request completes successfully, the REXX stem variable is populated with the command response that is returned by OM. The REXX program can then refer to the command response and take appropriate action.

token_name
The name of the command and response token (CART). The token name should match the name specified on the CART subcommand.

wait_time
A timeout value for the CSLULGTP command. The CSLULGTP command waits until the command completes, but the wait lasts only as long as the time specified. The wait time is in the format MMMMM:SS or sssss. Enclose this value in quotes.

The maximum timeout value is 99999:59. If you do not specify a value for this parameter, the command times out after a very short delay of less than one tenth of a second.
IMS checks whether the command completed or timed out every 0.01 seconds if the value of `wait_time` is less than ten seconds. If the value is larger than ten seconds, IMS checks every second instead.

This timeout value is not the same as the timeout value for the WAIT subcommand; however, the value of `wait_time` should be at least as long as the value specified on the WAIT subcommand. Otherwise, no command response are received for long running commands.

If no response is received the first time, you can issue the CSLULGTP command again.

Intermittent results can occur when `stem_name`, `token_name`, and `wait_time` parameters are not coded on the CSLULGTP call.

**Sample code for retrieving command responses using the CSLULGTP request**

The following examples provide a code sample of the CSLULGTP request.

Example #1: In the example, the IMS command QRY TRAN NAME(A) is issued, and the CSLULGTP request is used to retrieve the command response.

```plaintext
Address LINK 'CSULULXS8'
Address IMSSPOC
  "ims PLEX1"
  "wait 5:00"
cartid = 'PROD12'
  "CART" cartid
  "QRY TRAN NAME(A*)"
results = cslulgtp('qinfo.', cartid,"5:00")
If qinfo.ctl.rc = 0 Then
  Do
    say "OM name =("qinfo.ctl.omname")"
    say "command master =("qinfo.cmd.master")"
  End
```

Example #2: This program issues the IMS UPD PGM command and processes the command responses. The following actions are taken based on the completion code:

- **0** - OK - say command complete for program 'program name'
- **10** - not found - issue CRE PGM command
- **73** - PSB scheduled - issue /DIS ACT REG command
- **other completion code** - say invalid CC for program

```plaintext
#ifndef REXX
#define REXX
#endif

/*-------------------------------------------------------------*/
| Establish IMS rexx environment. |
/*-------------------------------------------------------------*/

Address LINK 'CSULULXS8'
Address IMSSPOC
  "ims PLEX1"
  "WAIT 5:00"
  "CART CMDTOKEN"

/*-------------------------------------------------------------*/
| Issue an IMS command |
/*-------------------------------------------------------------*/

  "UPD PGM NAME(APOL1,BMP255,PGMX,PGMY) SET(SCHDTYPE(SERIAL))"

/*-------------------------------------------------------------*/
| Get command responses |

</tbody>
</table>

Where the suffix variables:

- **stem** user-defined stem name
- **x** row number of command response
- **y** column number of command response
The CSLULGTP function creates a report as part of the stem variable. The stem is any user provided value; the suffix is “report”.

```
"QRY TRAN SHOW(PSB,QCNT)"
results = cslulgtp('friday_status.', cartid,'1:30')
If friday_status.report.0 > 0 Then
  Do
    say friday_status.report.0
  Do x = 1 to friday_status.report.0
  say friday_status.report.x
End
End
```

The program would have results like this, where each line of the stem has a line of a formatted report.

```
6
Response for: QRY TRAN SHOW(PSB,QCNT)
Trancode MbrName CC PSBname QCnt LQCnt
ADDINV IMS2 0 0
ADDINV IMS2 0 DFSSAM04 2
ADDINV SYS3 0 DFSSAM04 1
ADDPART IMS2 0 0
```

### Handling errors when using the CSLULGTP function

The CSLULGTP function will not set the “ctl.rc” and “ctl.rsn” stem variables if an error is encountered in the function itself. It is therefore highly recommended that any REXX program that uses the CSLULGTP function first check the IMSRC and IMSREASON REXX variables before any other processing continues to determine whether the function completed successfully.

If the IMSRC variable is nonzero, and the error was encountered in CSLULGTP itself, the value in IMSRC will begin with “08”. In this case, the “ctl.rc” and “ctl.rsn” stem variables are not set and no data is returned in the stem variables.

The IMSRC and IMSREASON errors that can be returned are documented in the macro CSLUXRR.

For other errors (where the IMSRC variable is nonzero and does not begin with “08”), the “ctl.rc” and “ctl.rsn” stem variables will contain the command return code and reason code, and some of the other stem variables are set based on the command response. For example, if an invalid verb was entered, no command response data will be returned, but the “ctl.rc” and “ctl.rsn” stem variables as well as the REXX IMSRC and IMSREASON variables will be set.

### REXX SPOC API within a transaction

Transactions can be written in the REXX language. A REXX EXEC runs as an IMS application and has characteristics similar to other IMS-supported programming languages. The REXX SPOC API can be used to issue commands from a transaction and to examine the command responses.

In the IMS Adapter for REXX environment, the OM API command authorization is performed with the MPP user ID. To use the transaction origin user ID rather than MPP user ID, a user exit must be utilized. The Build Security Environment user exit (BSEX) is called for non-OTMA/non-APPC input messages. The exit can request that IMS build a security environment in the MPP region when a message is scheduled (an accessor environment element (ACEE) will be anchored on TCBSENV). After use of the exit, the transaction origin user ID is used for OM API
security checking. OTMA/APPc messages are not supported unless
SECURITY=FULL or SECURITY=PROFILE, and the selection for the input message
is FULL.

Related concepts:

IMS Adapter for REXX reference (Application Programming APIs)

Ending the IMS SPOC environment

By issuing the END subcommand, you can end the IMS SPOC environment when
you no longer want to execute IMS commands and signify that the SPOC
environment is no longer needed.

Use the END subcommand to signify that the SPOC environment is no longer
needed. After the END subcommand is issued, the control blocks associated with
the SPOC environment are freed.

END is a valid IMS command. If you specify the END command with no
operands, it is treated as an IMS SPOC subcommand. If you specify the END
command with parameters, it is sent to the IMSplex for processing as an IMS
command.

►►END◄◄

Retrieving unsolicited messages

After you set up the environment with CSLULXSB, you can use the CSLULSUB,
CSLULSUB, and CSLULGUM functions to subscribe to OM for unsolicited output
messages.

CSLULSUB request

By issuing the CSLULSUB request, you can start the subscription and monitor OM
for unsolicited messages.

►►CSLULSUB——(—IMS plex_name—,—member_list—,—type_list—)◄◄

Parameters for the CSLULSUB request

IMS plex_name

Name of the IMSplex. Do not use the ‘CSL’ prefix.

member_list

Specifies a list of member names of command processing clients in the
IMSplex (such as IMS control regions) from which this OM client will
receive unsolicited output messages. Do not specify this parameter if you
specify the type list parameter. If you do not specify a member list or a
type list, this OM client subscribes to all of the command processing clients
in the IMSplex. Enclose the list in quotes and separate names with
commas.

type_list

Specifies a type list of command processing client types (such as OM, RM,
and IMS) from which this OM client will receive unsolicited output
messages. Do not specify this parameter if you specify the member list
parameter. If you do not specify either a member list or a type list, this
OM client subscribes to all of the command processing clients in the IMSplex. Enclose the list in quotes and separate names with commas.

**CSLULUSB request**

By issuing the CSLULUSB request you can end the subscription. If a subscription does not exist, OM is no longer monitored for unsolicited messages.

```plaintext
>>> CSLULUSB ("--- IMS plex_name ---")
```

**Parameters for the CSLULUSB request**

*IMS plex_name*

Name of the IMSplex. Do not use the 'CSL' prefix.

**CSLULGUM request**

By issuing the CSLULGUM request you can copy unsolicited output messages to the REXX program variable named *stem_name*. The REXX program can then examine the messages and take appropriate action.

```plaintext
>>> CSLULGUM ("--- IMS plex_name ---, --- stem_name ---")
```

**Parameters for the CSLULGUM request**

*IMS plex_name*

Name of the IMSplex. Do not use the 'CSL' prefix.

*stem_name*

Name of a REXX variable that contains any unsolicited messages that are received. A stem variable is an array of values, with the '.0' element (for example 'mystem.0') indicating how many elements are in the array.

**Sample program for subscribing to OM**

This REXX SPOC API sample program uses CSLULSUB, CSLULBGMUM, and CSLULUSB to subscribe to OM and to retrieve unsolicited messages. The program shows how you can invoke unsolicited output message functions.

```rexx
/* rexx */

   The XML statements returned are put in the stem variable
   specified by the user.
--------------------------------------------------------------*/
spoc_rc = cslulgts('DISINFO.','DISTRAN','59')
do z1 = 1 to DISINFO.0
   /* display each line of XML information */
   Say disinfo.z1
end
"END"

REXX SPOC batch job example

These examples provide a sample batch job, a sample REXX SPOC program, and
job output from the REXX SPOC example.

Sample REXX SPOC batch job

The batch job shown in the following figure calls the batch TSO command
processor to get a response that contains all transactions that start with the letter V.

//REXXSPOC JOB ,
// MSGCLASS=H,NOTIFY=USRT002,USER=USRT002,TIME=(,30)
/*
//SPOC EXEC PGM=IKJEFT01,DYNAMNBR=45
//STEPLIB DD DISP=SHR,DSN=IMS.SDFSRESL
//SYSPROC DD DISP=SHR,DSN=LOCAL.IMS.CLIST
//SYSTSRT DD SYSOUT=A
//SYSTSIN DD *
%REXXSPOC QRY TRAN NAME(V*)
*/EOF
The DD names in this batch job include:

**STEPLIB**
Contains the load modules.

**SYSPROC**
Contains the REXX programs.

**SYSTSPRT**
Contains the output produced by the REXX program.

**SYSTSIN**
Contains the command to execute, including its parameters.

The QRY TRAN command in the JCL is passed as an argument to the following sample REXX program. The command is issued, and the response is sent to the SYSTSPRT file.

**REXX SPOC sample program**

The following figure shows the sample REXX program, REXXSPOC.

```rexx
/* rexx */
parse upper arg theIMScmd
Address LINK 'CSULXLXSB'
if rc = 0 then
  do
    Address IMSSPOC
    "IMS plxx1" ; if rc > 0 then say 'rc='imsrc 'reason='imsreason
    "route ims2"; if rc > 0 then say 'rc='imsrc 'reason='imsreason
cartid = "TEST13"
"cart" cartid ; if rc > 0 then say 'rc='imsrc 'reason='imsreason
"WAIT 1:00" ; if rc > 0 then say 'rc='imsrc 'reason='imsreason
theIMScmd
if rc > 0 then say 'rc='rc 'imsrc='imsrc 'reason='imsreason
  do
    results = cslulgts('TEMP.', cartid,"1:30")
    say 'results='results 'imsrc='imsrc 'reason='imsreason
    if temp.0 /= '' then
      do
        say 'temp.0'=('temp.0')'
        do idx = 1 to temp.0
          say 'temp.'idx'= 'temp.idx
        end
      end
    end
  end
"END"
End
exit
```

**Sample output**

The output from the REXXSPOC sample program is shown in the following output example.

```
READY
%REXXSPOC QRY TRAN NAME(V*)
results=00000000X imsrc=00000000X reason=00000000X
temp.0=(30)
temp.1= <imsout>
temp.2= <ctl>
temp.3= <omname>OM1OM </omname>
temp.4= <omvsn>1.1.0 </omvsn>
temp.5= <xmlvsn>1 </xmlvsn>
temp.6= <statime>2001.198 16:08:39.944953</statime>
temp.7= <stotime>2001.198 16:08:40.271944</stotime>
```
/DISPLAY command examples and format identifiers

This example illustrates how format identifiers (FID) can be returned when the REXX program issues the operator commands, /DISPLAY ACT and /DISPLAY STATUS.

This example shows how format identifiers (FID) can be returned on operator commands. The REXX program issues two commands: /DISPLAY ACT and /DISPLAY STATUS.

ADDRESS LINK 'CSULXSB'
ADDRESS IMSSPOC
"IMS PLEX1"
"CART DISCART1"
"DISPLAY ACT"
RSP_RC1= CSLULGTS('DISCART1', 'ACT1."

In this example using /DISPLAY ACT, the command response includes the FIDs, because the default is to provide the FIDs.

In the example that follows using /DISPLAY STATUS, the CSLULOPT function is invoked before the command is issued. The CSLULOPT function specifies that FIDs are not to be included in the command response. In the command response, no FIDs are included.

OPT_RC = CSLULOPT('NOFID')
"CART DISCART2"
"DISPLAY STATUS"
RSP_RC2= CSLULGTS('DISCART1', 'STAT1."

Autonomic computing examples

These examples illustrate autonomic computing capabilities associated with the REXX SPOC API. Autonomic indicates that the code is responsive and can take certain actions to correct what it determines to be incorrect.
**Autonomic example 1**

In the following example, a transaction is queried. If the transaction is stopped, the REXX SPOC API attempts to start it. The REXX SPOC API examines the information returned by CSLULGTS, looking specifically for the line that refers to the transaction of interest.

```plaintext
/* autonomic computing example 1 */
"CART qrytran12"
"qry tran name(CDEBTRN3) show(status)"
results = cslulgts("resp.","qrytran12","3:15")

Do idx = 1 to resp.0
   /* find which IMS and the status of tran */
   parse var resp.idx . "TRAN(CDEBTRN3)"
      "MBR(" imsnam ")",
      "LSTT(" status ")"
   /* if tran is stopped, try to start it */
   If pos('STOSCHD', status) > 0 Then
      Do
         /* send command to IMS that needs to restart tran */
         "ROUTE" imsnam
         "UPD TRAN NAME(CDEBTRN3) START(SCHD)"
      End
   End
End
```

**Autonomic example 2**

In the following example, the QUERY command is used to determine the queue count (qcnt) of a transaction. A qcnt with a value greater than 5 is considered a problem. The REXX SPOC API attempts to resolve the problem by starting another region and changing the transaction to a different class.

```plaintext
/* autonomic computing example 2 */
"CART qrytran13"
"qry tran name(sks1) show(qcnt)"
results = cslulgts("resp.", "qrytran13", "3:15")
Do idx = 1 to resp.0
   parse var resp.idx . "TRAN(SKS1) . "Q(" count ")" .
   If count = '' &
      count > 5 Then
      Do
         "CART strtrgn05"
         "START REGION IMSRG5"
         start? = cslulgts("strt.", "strtrgn05", "10:00")
         If imsrc = '00000000X' then
            Do
               "CART updtran14"
               "update tran name(SKS1) set(class(5))"
            End
         End
      End
   End
End
```

Chapter 10. REXX SPOC API and the CSL  287
Part 3. Asynchronous data propagation

You can propagate captured data asynchronously as an alternative to using the data capture exit routine. You can use this option to capture database changes for selected segment types and environment information in IMS data capture log records.

This alternative is available with the addition of a logging option on the EXIT= parameter of the DBDGEN utility. You can use the logging option to capture database changes for selected segment types and environmental information in IMS data capture log records. Captured information is compressed by using z/OS compression services to minimize the space that is needed to store the captured data on the IMS online data sets (OLDSs). After it is stored, the captured data is available for use; for example, to propagate to a DB2 for z/OS environment.

The data capture log records use the X'99' log code and have the following data capture subcodes to indicate the type of record that is being logged:

- X'04' Changed data
- X'28' End of job (EOJ)
- X'30' SETS call
- X'34' ROLS call

All data capture log records contain a common prefix, the Data Capture Log prefix, that contains the subcode that defines the type of record being logged. End of job records and SETS and ROLS call records consist entirely of this log record prefix and contain no additional information. Changed data log records, however, contain information in addition to the prefix and can span multiple physical log records to contain all of the captured data.

Chapter 11. Changed data log record

To retrieve all the data logged for a particular call, you must examine the physical log records to determine where the logical log record begins and ends. You can examine the changed data log record to view the captured data captured for a DL/I call.

For each DL/I call, there is one logical log record that comprises all the data requested for that call. However, because all the data might not fit in one log buffer, one logical log record can actually be composed of several physical log records. To retrieve all the data logged for a particular call, you must examine the physical log records to determine where the logical log record begins and ends.

The data captured for a DL/I call is stored as elements within the changed data log record. For each DL/I call, there are multiple data elements recorded in the changed data log record. The details of the data elements are described in the following topics.

Elements of captured data

Each data element contains a 4-byte header with metadata that describes the type and length of the data that follows the header.

The captured data elements are logged in the DCAP_DATA field within the changed data log record. The format of data elements is broken down into the header information and the actual logged data. See “Format for data element header” on page 300 for the format of the log record header.

Each data element contains a 4-byte header. The header contains a 1-byte LOGID field describing the type of data being logged in this element, a 1-byte LOG_FLAG and a 2-byte LOG_LL field. The LOG_LL field contains the length of the data that follows the header. This length is used to locate the header for the next element. The header is followed by the actual data defined in the LOGID field. The data is compressed using the z/OS/ESA compression services, if such services are available. If so, the COMPR_ALGORITHM field in LOG_DCAP_DATA indicates the algorithm used to compress the data.

If FLAG_1 of the changed data log record contains X'60' or X'E0' (FIRST_RECORD and FIRST_CALL flags set), the next data element is LOG_INQY_DATA. This element is only present in the first physical record of the logical log record.

The type of data element is identified in the LOGID field of the header and can be one of the following values:

LOGID X'00'
There is a CAPD block for each EXIT= logging request.

LOGID X'04'
The DBD version for the data base, as specified on the VERSION= parameter of the DBD macro during DBDGEN. A character string of up to 63 characters.
LOGID X'08'
The concatenated key for the segment in the CAPD. The format of the physical concatenated key is a character string of up to 3,824 (255 x 15) characters.

LOGID X'0C'
The capture data segment data block (CAPD_DATA). This block is used for captured segment data, which can be path data, segment data, or before-image data. There is a CAPD_DATA block for each segment that was captured for the call. The blocks are logged in the following order: path data, segment data, before-image data (replace), twin data (insert).

LOGID X'10'
The segment data for the path or segment data deleted, inserted, or replaced (for a replace, this data would represent the after-image). The length of the segment data is a character string of up to 30,700 characters.

LOGID X'14'
The before-image of the segment data changed by the replace operation. Only the first changed byte through the last changed byte is logged. The unchanged beginning and ending portions of the segment are reconstructed from the after-image contained in segment data. The before-image data is a halfword offset value (the offset of the changed data within the segment) followed by a character string of up to 30,700 characters. Only the actual before-image is compressed. The halfword offset value is not compressed. Within the changed data log record, there can be one before-image for every changed segment.

If all the data elements do not fit in a single log record, the next log record (with the same PST_NUMBER) contains the remaining data elements, starting where the previous record left off. Before-image data, however, is unique in that the offset (2 bytes) of the data in the segment is logged preceding the changed data. Therefore, the length of the data in DCAP_DATA (LOG_LL) is 2 bytes greater than the actual length of the data logged. The offset field is not compressed.

Related reference:

"CAPD_DATA format (LOGID=X'0C')" on page 304
"CAPD block format (LOGID=X'00')" on page 301

Reducing the amount of captured data

If the internal area of the changed data log record is not large enough to hold all of the data, the ERROR_LOG flag is set in the log record to indicate that the data is not complete. You can specify CASCADE,KEY,NODATA,NOPATH in the EXIT= parameter in the DBDGEN if cascade is required.

The changed data log record can contain a large amount of data for cascade deletes, especially when path data is requested. The data is staged in an internal area prior to logging. If this internal area is not large enough to hold all of the data, the ERROR_LOG flag is set in the log record to indicate that the data is not complete, although, the IMS data is committed and the call completes normally.

To avoid large amounts of data being written to the log and possible incomplete log records, specify CASCADE,KEY,NODATA,NOPATH in the EXIT= parameter in the DBDGEN if cascade is required. This specification results in just the concatenated key being written to the log during DLET operations, which significantly reduces the amount of data that is captured during a cascade delete.
For data propagation to DB2 for z/OS where the primary key is derived from the concatenated key, the segment data is not required for the delete in DB2 for z/OS.

**Example of logged data elements**

Changed data log records contain many data elements as a result of a call. This topic provides an example where a third-level segment is replaced and path data is requested to be logged.

Consider a situation where a third-level segment is replaced and path data is requested to be logged (Root segment is A, second-level segment is B, and the replaced segment is C). In this situation, the data elements are logged in the following order:

1. CAPD
2. DBD Version ID
3. Physical concatenated key
4. CAPD_DATA block for A
5. Segment data for A
6. CAPD_DATA block for B
7. Segment data for B
8. CAPD_DATA block for C
9. Segment data for C
10. CAPD_DATA block for C (before data)
11. Before-image data for C

If path data had not been requested, the CAPD_DATA blocks and segment data elements for A and B would not be logged.
Chapter 12. End of Job (EOJ) call log record

The EOJ call log record (X’28’ subcode) is written when a batch DL/I program that has written changed data log records terminates normally. The record is written to indicate that the updates have been committed, because a commit record is not written to the log when a batch job terminates.

Related reference:

“End of Job call log record format” on page 305
Chapter 13. SETS and ROLS call log records

The SETS (X'30' subcode) and the ROLS (X'34' subcode) call log records are written whenever an application that might cause data to be captured issues a SETS or ROLS call using a token.

The log records are written to indicate that any changed data log records written after the SETS call for the token used in the ROLS call will have been aborted (backed out). The records are written even if exits are defined without a logging request.

Related reference:
“SETS and ROLS call log record format” on page 305
Chapter 14. Format of the data capture log records

The topics in this section describe the format of the data capture log records.

Data capture log record prefix

The data capture log record prefix contains fields that describe the length, data capture subcode, recovery token, and CPU store clock time stamp of the log record.

The following table lists the prefix for data capture log records.

<table>
<thead>
<tr>
<th>Field name</th>
<th>Data type</th>
<th>Field description</th>
</tr>
</thead>
<tbody>
<tr>

Changed data log record format

The changed data log record contains fields that describe the first and last log records written for the call, the user ID for the call, the data element that is being logged, and other information regarding the log record.

The following table lists the record formats for changed data log records.

<table>
<thead>
<tr>
<th>Field name</th>
<th>Data type</th>
<th>Field description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FLAG_1</td>
<td>XL1</td>
<td>Flag 1: Bit definitions follow:</td>
</tr>
<tr>
<td>LAST_RECORD</td>
<td>X'80'</td>
<td>The last log record written for this call. If this bit is not on, the remaining data for this DL/I call is in the log records that follow.</td>
</tr>
<tr>
<td>FIRST_RECORD</td>
<td>X'40'</td>
<td>The first log record written for this call. If this bit is not on, the data logged at LOG_DATA_OFFSET is the data that would not fit in the preceding record.</td>
</tr>
<tr>
<td>FIRST_CALL</td>
<td>X'20'</td>
<td>The first log record written for this unit-of-recovery, so LOG_INQY_DATA is present in this log record. (FIRST_RECORD is on.)</td>
</tr>
<tr>

Part 4. Database resource adapter (DRA)

The DRA is an interface to IMS DB full-function databases and data entry databases (DEDBs). Your application designer can create a program so that the DRA can be used by a coordinator controller (CCTL) or a z/OS application program that uses the Open Database Access (ODBA) interface.

These topics are intended for the designer of a CCTL or an z/OS application program. If you want more information about a specific CCTL's interaction with IMS DB or DB/DC, see the documentation for that CCTL.

Related concepts:

- Writing ODBA application programs (Application Programming)

Related tasks:

- Accessing IMS databases through the ODBA interface (Communications and Connections)
Chapter 15. Thread concepts

A DRA thread is a DRA structure that connects a CCTL task or a z/OS application program task with an IMS DB task that can process those calls. A single DRA thread is associated with every CCTL or ODBA thread. CCTL threads cannot establish a connection with more than one DRA thread at a time.

A DRA thread is a DRA structure that connects:

- A CCTL task (which makes database calls to IMS DB) with an IMS DB task that can process those calls. A CCTL thread is a CCTL task that issues IMS DB requests using the DRA.
- A z/OS application program task (which makes database calls to IMS DB) with an IMS DB task that can process those calls. An ODBA thread is a z/OS task that issues IMS DB calls using the DRA.

A single DRA thread is associated with every CCTL or ODBA thread. CCTL threads cannot establish a connection with more than one DRA thread at a time.

When the DRA Open Thread option is used, threads sign on to IMS when they are scheduled for a request. This behavior causes the IMS commands /DISPLAY CSTL, /DISPLAY ACTIVE REGION and /DISPLAY ACTIVE THREAD to show different values for the MINTHRD output field compared to a non-Open Thread system configuration. Because thread TCBs are not attached, MINTHRD does not apply to the number of threads attached at DRA initialization. However, it does indicate how many thread structures IMS allocates during initialization. After IMS begins scheduling PSBs, those threads appear in the command output as normal.

Processing threads

The way that the DRA processes a CCTL thread is different from how it processes an ODBA thread. In each case, the CCTL or z/OS application program issues a request through the creation of a DRA thread or the allocation of a DRA thread block, respectively.

Processing a CCTL thread

When a CCTL application program needs data from an IMS DB database, a CCTL task must issue a SCHED request for a PSB. To process the SCHED request, the DRA must create a DRA thread. To do this, the DRA chooses an available DRA thread TCB and assigns to it the CCTL thread token (a unique token that CCTL puts in the SCHED PAPL PAPLTTOK) and its own IMS DB task, which schedules the PSB. If the scheduling is successful, the DRA thread connection is considered complete because it now connects a CCTL thread to an IMS DB task using a specific DRA thread TCB.

Subsequent DRA requests from this CCTL thread must use the same CCTL thread token in order to ensure that the request goes to the correct DRA thread. When the application program finishes and the CCTL thread no longer needs the services of the DRA thread, the CCTL issues a TERMTHRD (Terminate Thread) request to remove the CCTL thread token from the DRA thread TCB and terminates the DRA thread. The thread TCB can then become part of a new DRA thread.
Processing an ODBA thread

When a z/OS application program needs data from an IMS database, an ODBA task must issue an APSB call to initialize the ODBA environment. To process the APSB call, the DRA allocates a DRA thread block and assigns to it the ODBA thread and its own IMS DB task, which schedules the PSB. If the scheduling is successful, the DRA thread connection is considered complete because it now connects an ODBA thread to an IMS DB task using a specific DRA thread block.

When the application program finishes and the ODBA thread no longer needs the services of the DRA thread, the ODBA application issues a DPSB call to terminate the DRA thread. The thread block can then become part of a new DRA thread.

Processing multiple threads

The ability of the DRA to process more than one thread at the same time is known as multithreading. Multithreading means that multiple CCTL or ODBA threads can be using the DRA at the same time. Multithreading applies to all DRA requests and ODBA calls.

Processing multiple CCTL threads

To use the multithreading capability:
  - The DRA must be initialized with more than one thread TCB. To initialize the DRA with more that one thread TCB, specify the MAXTHRD parameters (in the DRA Startup Table) as greater than one.
  - The CCTL must be capable of processing its CCTL threads concurrently.
  - The CCTL must have Suspend and Resume exit routines. The DRA uses these routines to notify the CCTL of the status of thread processing.

Processing multiple ODBA threads

To use the multithreading capability, the DRA must be initialized with more than one DRA thread. To do this, specify the MAXTHRD parameters (in the DRA Startup Table) as greater than one.

CCTL multithread example

This example illustrates the concept of concurrent processing in a multithreading system.

Events in a multithreading system are shown in chronological order from top to bottom in the following example. To illustrate the concept of concurrent processing, the figure is split into two columns.

There are two CCTL threads and two DRA threads in the example. CCTLRRTNA is the module name (for this example) of the CCTL routine that builds PAPLs and calls DFSPPRC0 to process DRA requests.

</tr>
<tr>
<td>• DFSPRRC0 calls the Suspend exit routine.</td>
<td></td>
</tr>
<tr>
<td>• The Suspend exit routine suspends CCTL thread1.</td>
<td></td>
</tr>
</tbody>
</table>

CCTL can now dispatch other CCTL threads for the CCTL TCB. Application program2 needs a PSB, so CCTL thread2 is created.

CCTL thread2 events:

<table>
<thead>
<tr>
<th>CCTL TCB events</th>
<th>DRA TCB events</th>
</tr>
</thead>
<tbody>
<tr>
<td>• CCTLRTNA builds the SCHED PAPL and calls DFSPRRC0.</td>
<td>DRA thread TCB2 events:</td>
</tr>
<tr>
<td>• DFSPRRC0 creates a DRA thread, and a new thread token (PAPLTTOK) is assigned to DRA thread TCB2.</td>
<td>• The DRA processes the SCHED request and asks IMS DB to perform a schedule process.</td>
</tr>
<tr>
<td>• DFSPRRC0 activates thread TCB2.</td>
<td>• Scheduling is in progress.</td>
</tr>
<tr>
<td>• DFSPRRC0 calls the Suspend exit routine.</td>
<td></td>
</tr>
<tr>
<td>The Suspend exit routine suspends CCTL thread2.</td>
<td></td>
</tr>
</tbody>
</table>

Both threads are now suspended. The CCTL TCB is inactive until one of the threads resumes execution.

Thread2 can resume immediately because the CCTL TCB is idle. Execution resumes directly after the point at which the thread was suspended by the Suspend exit routine.

DRA thread TCB2 events:

<table>
<thead>
<tr>
<th>CCTL TCB events</th>

</tbody>
</table>
Table 79. Example of events in a multithreading system (continued)

CCTL TCB events

- The Suspend exit routine suspends CCTL thread1.

Application program2 completes. The CCTL makes sync-point requests to IMS DB to commit the processing of this UOR. The CCTL flags the UOR for application program2 as in-doubt prior to issuing a phase 1 request. The CCTL keeps a record of this in-doubt UOR until the CCTL can make a successful phase 2 call to IMS DB.

CCTL thread2 events:

- CCTLRTNA issues a PREP request and calls DFSPRRC0.
- DFSPRRC0 activates thread TCB2.
- DFSPRRC0 calls the Suspend exit routine.
- The Suspend exit routine suspends CCTL thread2.

The PREP request results are returned to CCTLRTNA (by the PREP PAPL), and thread2 becomes inactive.

CCTL thread1 events:

- After thread1 has been resumed, control is passed back to CCTLRTNA.

DRA TCB events

DRA thread TCB1 events:

- The DL/I call is in progress.
- The DRA processes the DL/I PAPL and asks IMS DB to perform a DL/I process.

DRA thread TCB2 events:

- The DRA sends the PREP request to IMS DB.
- IMS DB logs Phase 1 complete. This IMS DB UOR is now in-doubt.
- The PREP request completes successfully and calls the Resume exit routine.

DRA thread TCB1 events:

- IMS DB detects a DL/I failure. This failure results in termination of this DRA thread and a termination of this thread TCB.
- Since this thread was in a schedule state, the DRA calls the Status exit routine and passes the DL/I PAPL back to the CCTL after putting UPSTOR information in it.
- The Status exit routine associates UPSTOR with a CCTL thread, and the routine passes the PAPL to the DRA.
- The DRA calls the Resume exit routine.
- The DRA takes an SDUMP and terminates thread TCB1.
### Table 79. Example of events in a multithreading system (continued)

Chapter 16. Sync points

Sync point processing finalizes changes to resources. Sync point requests specify actions to take place for the resource changed (for example, commit or abort). A sync point is when IMS DB actually processes the request.

Each sync point is based on a unit of recovery (UOR). A UOR covers the time during which database resources are allocated and can be updated until a request is received to commit or abort any changes. Normally, the UOR starts with a CCTL SCHED (schedule a PSB) request or an ODBA APSB call and ends with a sync point request. Other DRA thread requests can also define the start and end of a UOR.

A CCTL UOR is identified by a recovery token (PAPLRRTOK) that is received as part of a thread request that creates a new UOR. It is 16 bytes in length. The first 8 bytes contain the CCTL identification. This identification is the same as the CCTL ID that was a final DRA startup parameter determined from USERID or PAPLUSID in INIT request. The second 8 bytes must be a unique identifier specified by the CCTL for each UOR.

Related Reading: See the request descriptions under Chapter 22, “CCTL-initiated DRA function requests,” on page 333 for more information on the DRA thread requests.

IMS DB expects the CCTL or the ODBA application to make the sync point decision and the resulting request. In the case of a CCTL, the CCTL is the sync point manager and coordinates the sync point process with all of the database resource managers (including those other than IMS DB) that are associated with a UOR. In the case of an ODBA application, z/OS Resource Recovery Services is the sync point manager and coordinates all the resource managers (including those other than IMS) that are associated with the UOR.

A CCTL working with a single resource manager may request a sync point in a single request or can use the two-phase sync point protocol which is required for a CCTL working with multiple resource managers. The single-phase sync point request can be issued when the CCTL has decided to commit the UOR, and when IMS DB owns all of the resources modified by the UOR.

An ODBA application must use the two-phase sync point protocol for committing changes to the IMS database.

Related reference:
“SCHED request” on page 338
“SYNTERM request” on page 342
“PREP request” on page 343
“COMTERM request” on page 344
“ABTTERM request” on page 345
The two-phase commit protocol

The two-phase sync point protocol consists of two requests issued by the sync point manager to each of the resource managers involved in the UOR. Each of the UOR states, in-flight and in-doubt, define what happens to the UOR in the event of a thread failure.

Phase 1
The sync point manager asks all participants if they are ready to commit a UOR.

Phase 2
The sync point manager tells each participant to commit or abort based on the response to the request issued in phase 1.

A UOR has two states: in-flight and in-doubt. The UOR is in an in-flight state from its creation time until the time IMS DB logs the phase 1 end (point C in the following two tables). The UOR is in an in-doubt state from (point C) until IMS DB logs phase 2 (point D in the following two tables).

The in-doubt state for a single-phase sync point request is a momentary state between points C and D in Table 1.

The in-flight and in-doubt states are important because they define what happens to the UOR in the event of a thread failure. If a thread fails while its IMS DB UOR is in-flight the UOR database changes are backed out. If a thread fails when its IMS DB UOR is in-doubt, during single-phase commit, the UOR database changes are kept for an individual thread abend, but are not kept for a system abend. If a thread fails when its IMS DB UOR is in-doubt during two-phase commit, the database changes are kept.

Thread failure refers to either of these cases:
- Individual thread abends.
- System abends: IMS DB failure, CCTL failure, ODBA application failure, or z/OS failure (which abends all threads).

The following code shows the system events that occur when CCTL is used for single-phase sync point processing.

```
<table>
<thead>
<tr>
<th>Time</th>
<th>Points In Time</th>

The following figure shows the system events that occur when two-phase sync point processing is completed using ODBA.

![Figure 8. ODBA two-phase sync point processing](image)

**Note:**
1. The ODBA application and IMS DB make a connection using the ODBA interface.
2. IMS expresses protected interest in the work started by the ODBA application. This informs z/OS Resource Recovery Services that IMS will participate in the two-phase commit process.
3. The ODBA application makes a read request to an IMS resource.
4. The ODBA application updates a protected resource.
5. Control is returned to the ODBA application following its update request.
6. The ODBA application requests that the update be made permanent by issuing the SRRCMIT call.
7. RRS calls IMS to do the prepare (phase 1) process.
8. IMS returns to RRS with its vote to commit.
9. RRS calls IMS to do the commit (phase 2) process.
10. IMS informs RRS that it has completed phase 2.
11. Control is returned to the ODBA application following its commit request.

---

### In-doubt state during two-phase sync processing

A IMS DB UOR remains in the in-doubt state until a phase 2 request is received. This process is called “resolving the in-doubt”. While a UOR is in-doubt, the database resources owned by that UOR are inaccessible to other requests. It is vital that in-doubts are resolved immediately.

### CCTL example

If in-doubt UORs are created because IMS DB failed, the following sequence must occur to resolve the in-doubt UORs.

1. After restarting IMS DB, the CCTL should identify itself to IMS DB using an INIT request.
2. If identification is successful, the DRA notifies the CCTL control exit, passing to it a list of IMS DB UORs that are in-doubt.
3. The CCTL must resolve each in-doubt by making a RESYNC call, which causes a phase 2 action, commit or abort.
4. For CCTL to resolve a IMS DB in-doubt UOR, the CCTL must have a record of this UOR and the appropriate phase 2 action it must take. In this example, the CCTL record of a possible IMS DB in-doubt UOR is called a transition UOR.
5. The CCTL must define a transition UOR for the interval A-K (refer to Table 81 on page 319). Because this interval encompasses the IMS DB in-doubt period C-H, CCTL can resolve any in-doubts.

If a CCTL defines a transition UOR as interval E-K and if IMS DB fails while a thread is between C and D, IMS DB has an in-doubt UOR for which CCTL has no corresponding transition UOR, even though the phase 1 call failed. CCTL cannot resolve this UOR during the identify process. The only way to resolve this in-doubt is by using the IMS DB command, /CHANGE CCTL.

For ODBA, all in-doubts are resolved through z/OS Resource Recovery Services.
Chapter 17. DRA startup table

The database resource adapter (DRA) Startup Table contains values used to define the characteristics of the DRA. You must make the required changes to these modules to correctly specify the DRA parameters.

The DRA Startup Table is created by assembling:
• The DFSPZPxx module for a CCTL’s use.
• The DF5xxxx0 module for ODBA’s use.

The CCTL or ODBA system programmer must make the required changes to these modules to correctly specify the DRA parameters. The DRA parameters are specified as keywords on the DFSPRP macro invocation.

Sample DFSPZP00 source code
DFSPZP00 CSECT
DFSPRP  DSECT=NO,FPBUF=10,FPBOF=5,CNBA=60,MINTHRD=3,MAXTHRD=6,DSNAME=IMS.SDFSRESL
END

DFSPRP macro keywords

Keyword  Description
AGN=   This keyword is no longer used. If specified, it is ignored.
CNBA=   Total Fast Path NBA buffers for the CCTL’s or ODBA’s use.
DBCTLID=   The four-character name of the IMS DB or DB/DC region. This is the same as the IMSID parameter in the DBC procedure. The default name is SYS1.
DDNAME=   A 1-to-8 character ddname used with the dynamic allocation of the IMS DB execution library. The default ddname is CCTLDD.
DSNAME=   A 1-to-44 character data set name of the IMS DB execution library, which must contain the DRA modules and must be z/OS authorized. The default DSNAME is IMS.SDFSRESL. This library must contain the DRA modules.
FPBOF=   The number of Fast Path DEDB overflow buffers allocated per thread. The default is 00.
FPBUF=   The number of Fast Path DEDB buffers allocated and fixed per thread. The default is 00.
FUNCLV=   Specifies the DRA level that the CCTL or ODBA supports. The default is 3.
GENSNAP=   Specifies whether to produce or suppress SNAP output in DFSPAT20 during thread termination.
YES Produces SNAP output in DFSPAT20 during thread termination. YES is the default.

NO Suppresses the generation of SNAP output by DFSPAT20 during thread termination.

IDRETRY=
The number of times a z/OS application region is to attempt to IDENTIFY (or attach) to IMS after the first IDENTIFY attempt fails. The maximum number is 255. The default is 0.

IMSPLEX=
A 1- to 5-character user-specified identifier that is concatenated to 'CSL' to create the z/OS cross-system coupling facility CSL IMSPLEX group name. The value specified here must match the IMSPLEX NAME= value specified in the SCI startup procedure. The IMS ODBA interface uses this XCF CSL IMSPLEX group to register with SCI using the CSLSCREG interface; the target ODBM address space must specify the same XCF CSL IMSPLEX group name when registering with SCI. If you specify this parameter, the IMS ODBA interface routes calls to the ODBM address space rather than directly to IMS. If IMSPLEX= is not specified, ODBA calls are routed directly to IMS.

This parameter is required for applications that route ODBA calls through the ODBM address space. There is no default value.

MAXTHRD=
The maximum number of DRA thread TCBs available at one time. The maximum number is 4095. The default is number 1.

MINTHRD=
The maximum number of DRA thread TCBs available at one time. The maximum number is 4095. The default is number 1.

When the DRA Open Thread TCB option is active, this value refers to the number of DRA threads that are signed on to IMS.

When the DRA Open Thread TCB option is inactive, this value refers to the number of DRA thread TCBs that remain attached and signed on to IMS.

ODBMNAME=
Specifies the name of the ODBM address space to which the ODBA interface registers using the CSLDMREG request, and to which the ODBA calls are routed using the CSLDMI interface. This is an optional parameter. There is no default. If ODBMNAME= is not specified, the ODBA interface selects which ODBM address space all ODBA calls are routed.

OPENTHRD=
Specifies whether or not to enable DRA Open Thread support processing. When enabled and using CICS® 4.2 or higher, this option directs the DRA not to attach dedicated IMS DRA thread task control blocks (TCBs). CICS TCBs are used instead, which are intended for increased parallelism within the CICS/DRA environment.

CCTL Open Thread processing is enabled.

DISABLE
Open Thread processing is disabled. This is the default.

SOD= The output class used for a SNAP DUMP of abnormal thread terminations. The default is A.
TIMEOUT=
(CCTL only). The amount of time (in seconds) a CCTL waits for the
successful completion of a DRA TERM request. Specify this value only if
the CCTL application is coded to use it. This value is returned to the CCTL
upon completion of an INIT request.

TIMER=
The time (in seconds) between attempts of the DRA to identify itself to
IMS DB or DB/DC during an INIT request. The default is 60 seconds.

TIMETHREADCPU=
Specifies whether the DRA monitors and reports the CPU usage statistics,
that are related to DRA threads, when DRA Open Thread support is
enabled. The time is reported in IMS 07 log record DLRTIME field, and to
the CCTL in DRA thread statistics field PAPLCTM1.

YES The DRA monitors and reports the CPU usage statistics. A value of
YES overrides any value that is specified by the CCTL. YES is the
default.

NO The DRA does not monitor and report the CPU usage statistics. A
value of NO overrides any value that is specified by the CCTL.

CLIENT
The DRA uses the setting that is specified by the DRA client
through the INIT call (YES or NO) . If the client does not specify a
setting, YES is the default.

USERID=
An 8-character name of the CCTL or ODBA region. This keyword is
ignored for an ODBA Region.

Chapter 18. Enable the DRA for a CCTL

Two main steps are required to enable the DRA for a CCTL. After both steps are completed, the DRA is capable of handling other requests.

This section describes the two steps required to enable the DRA.

1. The coordinator controller (CCTL) system must load the DRA Startup/Router routine (DFSPRRC0) into a CCTL load library. Although DFSPRRC0 is shipped with the IMS product, it runs in the CCTL address space. Also, The version of the IMS DRA modules that are used by the CCTL must be the same version as the IMS with which the CCTL is communicating.

   Recommendations:
   • Concatenate the IMS.SDFSRESL library to the CCTL step library so the correct version of the DRA Startup/Router routine (DFSPRRC0) is loaded into the CCTL load library.
   • Ensure that the DRA Startup Table (DFSPZPxx) points to the correct version of IMS.SDFSRESL.

2. The system programmer must put the DFSPZPxx load module in a load library. The DRA is now ready to be initialized.

The CCTL starts the initialization process as a result of the CCTL application program issuing an initialization (INIT) request. At this point in time, the CCTL loads DFSPRRC0 and then calls the DRA to process the INIT request.

As part of the initialization request, the CCTL application program specifies the startup table name suffix (xx). The default load module, DFSPZP00, is in the IMS.SDFSRESL library.

After processing the INIT request, the DRA identifies itself to IMS DB. The DRA is then capable of handling other requests.

DFSPZP00 contains default values for the DRA initialization parameters. If you want to specify values other than the defaults, write your own module (naming it DFSPZPxx), assemble it, and load it in the CCTL load library. Use the supplied module, DFSPZP00, as an example.

The remainder of the DRA modules reside in a load library that is dynamically allocated by DFSPRRC0. The DDNAME and DSNAME of this load library are specified in the startup table. The default DSNAME (IMS.SDFSRESL) contains all the DRA code and is specified in the default startup table, DFSPZP00.

Related reference:
- Database resource adapter startup table for CCTL regions (System Definition)
- “INIT request” on page 333
Chapter 19. Enabling the DRA for the ODBA interface

Four steps are required to enable the DRA before an ODBA interface can use it. The first step is to create the ODBA DRA startup table.

There are four steps required to enable the DRA before an ODBA interface can use it:
1. Create the ODBA DRA Startup Table.
2. Verify that the ODBA and DRA modules reside in the STEPLIB or JOBLIB in the z/OS application region.
3. Link the ODBA application programs with DFSCDLI0.
4. Configure security.

The ODBA interface starts the initialization process after the ODBA application program issues either a CIMS INIT request or, if the ODBA application requires connections to multiple IMS systems, a CIMS CONNECT request. The CIMS INIT and CIMS CONNECT requests establish the ODBA environment in the address space. APSB requests then call the DRA to process the PSB schedule request with the IMS DB specified in DFSxxxx0, where xxxx is the DRA startup table name specified on the APSB call in the AIBRSNM2 field of the AIB.

After processing the CIMS INIT request or the CIMS CONNECT request, the DRA identifies itself to IMS DB if the optional xxxx value is passed on the CIMS INIT or CIMS CONNECT call. The DRA is then capable of handling other requests. The DRA’s structure at this time is shown in the following figure.

![Diagram](Figure 9. DRA component structure with the ODBA interface)

The remainder of the DRA modules reside in a load library that is dynamically allocated by DFSAERA0. The DDNAME and DSNAME of this load library are specified in the startup table. The default DSNAME (IMS.SDFSRESL) contains all the DRA code.

Database resource adapter startup table for CCTL regions (System Definition)

© Copyright IBM Corp. 1974, 2016
Chapter 20. Processing CCTL DRA requests

The CCTL communicates with IMS DB through DRA requests that are passed from the CCTL to the DRA using a participant adapter parameter list (PAPL). To make a DRA request the CCTL must pass control to the DRA Startup/Router Routine DFSPRRC0, and have register 1 point to a PAPL.

Before passing control to DFSPRRC0, the CCTL must fill in the PAPL according to the request. These requests are specified by a function code in the PAPLFUNC field.

To specify a thread function request, put the PAPLTFUN value into the PAPLFUNC field.

The function requests are further broken down into many subfunctions. A thread function request is referred to by its subfunction name (for example, a thread request with a schedule subfunction is referred to as a SCHED request). Non-thread function requests are referred to by function name (for example, an initialization request is called an INIT request).

The term “DRA request” applies to both thread and non-thread function requests.

Once the PAPL is built and the DRA Startup/Router routine is loaded, the CCTL passes control to DFSPRRC0. The contents of the registers upon entry to DFSPRRC0 are:

<table>
<thead>
<tr>
<th>Register</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Address of the PAPL</td>
</tr>
<tr>
<td>13</td>
<td>Address of a standard 18-word save area</td>
</tr>
<tr>
<td>14</td>
<td>Return address of the calling routine</td>
</tr>
</tbody>
</table>

The DRA Startup/Router routine puts itself into 31-bit addressing mode and will return to the calling routine in the caller’s original addressing mode with all its registers restored. Register 15 is always returned with a zero in it.

The return code for the request is in the PAPLRETC field of the PAPL.
Chapter 21. Processing ODBA calls

An ODBA application program communicates with IMS DB using the AERTDLI interface. The AERTDLI call interface processes DL/I calls from the ODBA application and also returns the results of those calls back to the ODBA using an AIB.

Unlike a CCTL's use of the PAPL, an ODBA application program communicates with IMS DB using the AERTDLI interface. The AERTDLI call interface processes DL/I calls from the ODBA application and also returns the results of those calls back to the ODBA using an AIB.

Related reference:

Specifying the AIB mask for ODBA applications (Application Programming)
Chapter 22. CCTL-initiated DRA function requests

Certain requests are available to the CCTL that allow it to communicate with DBCTL. For all DRA requests, there are PAPL fields that the CCTL must fill in. The PAPLUSER field is a field to be used at the CCTL's discretion. One possible use for it is to pass data to exit routines.

This topic contains General-use Programming Interface information.

For all DRA requests, there are PAPL fields that the CCTL must fill in. When the DRA completes the request, there are some output PAPL fields that the DRA fills in. Some fields in the returned PAPL might contain the original input value.

(The PAPLTTOK and PAPLUSER fields retain the original input values.)

The PAPLUSER field is a field to be used at the CCTL's discretion. One possible use for it is to pass data to exit routines.

The DRA returns a code (in the PAPLRETC field) to the CCTL after processing a DRA request. The code indicates the status of the request and can be either an IMS code, a DRA code, or a z/OS code. Failed DRA requests return a nonzero value in the PAPLRETC field.

To use the default Suspend exit routine and Resume exit routine, each DRA request must have the field PAPLTECB set with the address of a CCTL ECB to be used if the thread is waited or posted. If your CCTL does not provide Suspend and Resume exit routines, the DRA default exit routines will be used.

“Problem diagnosis” on page 354

Related reference:
DBCTL return codes (Messages and Codes)

INIT request

You can use the INIT request to initialize the DRA. The DRA startup parameter table contains all of the required parameters that you need to define the DRA. You can use the parameters given in the default module, DFSPZP00, or you can write your own module and bind it into the IMS.SDFSRESL data set.

The INIT PAPL also contains some parameters needed to initialize the DRA. If the same parameter appears in both the INIT PAPL and in the DRA startup parameter table, the specification in the INIT PAPL will override that in the startup table.

In addition to the required parameters of INIT PAPL, the optional parameters include:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLFUNC</td>
<td>PAPLINIT</td>
</tr>
<tr>
<td>PAPLSUSP</td>
<td>The address of the Suspend exit routine</td>
</tr>
</tbody>
</table>
PAPLRESM
The address of the Resume exit routine

PAPLTECB
To use the default Suspend exit routine and Resume exit routine, each
DRA request must have the field PAPLTECB set with the address of a
CCTL ECB to be used if the thread is waited or posted. If your CCTL does
not provide Suspend and Resume exit routines, the DRA default exit
routines will be used.

PAPLCNTL
The address of the Control exit routine

PAPLTSTX
The address of the Status exit routine

After the INIT request and the startup table have been processed, the DRA returns
the following data to the CCTL in the INIT PAPL:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLDBCT</td>
<td>The IMS DB identifier (this is the IMSID parameter from system definition)</td>
</tr>
<tr>
<td>PAPLCTOK</td>
<td>The request token that identifies the CCTL to the DRA</td>
</tr>
<tr>
<td>PAPLTIMO</td>
<td>DRA TERM request timeout value (in seconds)</td>
</tr>
<tr>
<td>PAPLRETC</td>
<td>A code returned to the CCTL specifying the status of the request</td>
</tr>
<tr>
<td>PAPLDLEV</td>
<td>A flag indicating to CCTL which functions the DRA supports. (For the latest version of PAPL mapping format see the IMS. library; member name is DFSPAPL.)</td>
</tr>
</tbody>
</table>

INIT request, identify to DBCTL

To make the DRA functional, the DRA must identify itself to IMS DB, thus
establishing a link between IMS DB and the CCTL. The identify process occurs in
two cases:
• As a direct result of an INIT request.
• As part of a terminate/reidentify request from a Control exit routine invocation.

The DRA identifies itself to the IMS DB subsystem specified in the final DRA
startup parameters. The identify process executes asynchronously to the INIT
process. Therefore, it is possible for the INIT request to complete successfully while
the identify process fails. In this case, the Control exit routine notifies the CCTL
that the connection to IMS DB failed.

If IMS DB is not active, the console operator will receive a DFS690 message (a code
of 0 was returned in the PAPLRETC field). You must reply with either a CANCEL
or WAIT response. If you reply with WAIT, the DRA waits for a specified time
interval before attempting to identify again. The waiting period is necessary
because the identify process will not succeed until the DBCTL restart process is
complete. You specify the length of the waiting period on the TIMER DRA startup
parameter. If subsequent attempts to identify fail, the console operator will receive
message DFS691, WAITING FOR IMS DB.
If the DRA cannot identify to IMS DB because the subsystem does not reach a restart complete state, there are two ways to terminate the identify process:

- The Control exit routine is called with each identify failure. This sets a PAPL return code of 4 or 8, terminating the identify process.
- The CCTL can issue a TERM request.

If you reply with CANCEL to message DFS690, control is passed to the Control exit routine, and the DRA acts upon the routine's decision.

After the identify process successfully completes, the DRA makes the CCTL address space non-swappable and calls the Control exit routine with a list of in-doubt UORs. If no in-doubt UORs exist, a null list is passed. The CCTL can use the RESYNC request to resolve any in-doubt UORs that do exist.

The INIT request attempts to create the MINTHRD number of thread TCBs. The actual number of TCBs created might be less than this value due to storage constraints.

**INIT request after a previous DRA session termination**

If a prior DRA session ended with a TERM request that received a PAPL return code=0, this INIT request must specify PAPLCTOK=0. If PAPLCTOK other than 0 is sent, the INIT request fails.

The INIT request must pass the PAPLCTOK value of the prior session in the current PAPLCTOK field if a DRA session ended because of:

- A nonzero return code from a TERM request.
- An internal TERM request from a Control exit routine request.
- A DRA failure.

**INIT request to use the DRA open thread TCB option**

The DRA open thread TCB allows the CCTL to direct the DRA not to attach dedicated DRA thread TCBs. Instead, DRA thread requests are processed on the CCTL application TCB.

The DRA open thread TCB option is either in use or not in use for the duration of the DRA instance.

To request activation of the DRA open thread TCB, set the following fields for the INIT request:

**PALPFNCL**

3 (PAPLFNC3)

**PAPLOOTT**

Set this bit (X’08’) to activate the open thread TCB.

You can verify that the TCB open thread is in use for the DRA by examining the PAPLDELEV flag field in the CCTL in INIT PAPL that the DRA returns after the INIT call. If the PAPLOTCB (X’08’) flag is set to 1, the open thread TCB option is in use.
INIT request to use the DRA open thread TCB option

When DRA open thread support processing is enabled, the DRA will or will not
monitor and report the CPU time usage statistics that are related to the DRA
thread processing based on the value specified for TIMETHREADCPU= on the
DFSPRP macro in DFSPZPxx member.

If anything other that TIMETHREADCPU=CLIENT is specified in the DFSPZPxx
member, the DRA ignores what is specified on the INIT call.

To request the DRA not to monitor CPU time usage statistics, set the following
fields for the INIT request:

PALPFNCL
3 (PAPLFNC3)

PAPLOTEN
Set this bit (X'20') in field PAPLDROP to disable DRA thread CPU time
usage statistics monitoring.

To determine if CPU usage statistics are being monitored for DRA thread
processing, check the PAPLDLEV flag field in the CCTL INIT PAPL that the DRA
returns after the INIT call. CPU usage statistics is not being monitored and
reported if the PAPLOTEN (x'40') flag is set to 1.

Related concepts:
Chapter 18, “Enable the DRA for a CCTL,” on page 325

RESYNC request

You can use the RESYNC request to tell IMS DB what to do with in-doubt UORs.
Four different subfunction values indicate possible actions for IMS DB to take for
the UOR.

The following subfunction values indicate possible actions:

PAPLRRCOM
Commit the in-doubt UOR.

PAPLRABT
Abort the in-doubt UOR. Changes made to any recoverable resource are
backed out.

PAPLSCLD
The UOR was lost to the transaction manager due to a coldstart.

PAPLSUNK
The in-doubt UOR is unknown to the CCTL. This can occur when the
CCTL’s in-doubt period does not include the start of phase 1. (See Table 81
on page 319 for an illustration of in-doubt periods.)

You must fill in the following input fields of the PAPL:

Field    Contents
PAPLCTOK    Request token
This token identifies the CCTL to the DRA. The DRA establishes the token and returns it to the CCTL in the parameter list on the startup INIT request. The request token must be passed on to the DRA for all RESYNC requests.

**PAPLRTOK**

Recovery token

This 16-byte token is associated with a UOR. The first 8 bytes must be the transaction manager subsystem ID. The second 8 bytes must be unique for one CCTL thread. This is one of the in-doubt recovery tokens passed to the Control exit routine.

**PAPLFUNC**

PAPLRSYN

**PAPLSFNC**

This field must contain PAPLRCOM, PAPLRABT, PAPLSCLD, or PAPLSDK.

In addition to the required input parameters, the optional input parameters include:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLTECB</td>
<td>To use the default Suspend exit routine and Resume exit routine, each DRA</td>
</tr>
<tr>
<td></td>
<td>request must have the field PAPLTECB set with the address of a CCTL ECB</td>
</tr>
<tr>
<td></td>
<td>to be used if the thread is waited or posted. If your CCTL does not provide</td>
</tr>
<tr>
<td></td>
<td>Suspend and Resume exit routines, the DRA default exit routines will be used.</td>
</tr>
</tbody>
</table>

**TERM request**

You can use the TERM request to terminate the IMS DB/CCTL connection and remove the DRA from the CCTL environment. The DRA terminates after all threads have been resolved. No new DRA or thread requests are allowed, and current requests in progress must complete.

You must fill in the following input fields in the PAPL:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLFUNC</td>
<td>PAPLTERM, DRA terminate function code</td>
</tr>
<tr>
<td>PAPLCTOK</td>
<td>The DRA request token (output from an INIT request)</td>
</tr>
</tbody>
</table>

In addition to the required input parameters, the optional input parameters include:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLTECB</td>
<td>To use the default Suspend exit routine and Resume exit routine, each DRA</td>
</tr>
<tr>
<td></td>
<td>request must have the field PAPLTECB set with the address of a CCTL ECB</td>
</tr>
<tr>
<td></td>
<td>to be used if the thread is waited or posted. If your CCTL does not provide</td>
</tr>
<tr>
<td></td>
<td>Suspend and Resume exit routines, the DRA default exit routines will be used.</td>
</tr>
</tbody>
</table>
After receiving the TERM request results, the CCTL might remove DFSPPRC0.

The fields returned in the PAPL to the CCTL are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLRETC</td>
<td>The return code</td>
</tr>
<tr>
<td>PAPLMXNB</td>
<td>The number of times the maximum thread count was encountered during this DRA session</td>
</tr>
<tr>
<td>PAPLMNTNB</td>
<td>The number of times the minimum thread count was encountered during this DRA session</td>
</tr>
<tr>
<td>PAPLHITH</td>
<td>The largest number of thread TCBs that were scheduled during this DRA session</td>
</tr>
<tr>
<td>PAPLTMX</td>
<td>The elapsed time at maximum thread for this DRA session</td>
</tr>
</tbody>
</table>

**SCHED request**

You can use the SCHED request to schedule a PSB in IMS DB. The first SCHED request made by a CCTL thread requires a new DRA thread. Existing DRA thread TCBs are used if they are not currently processing a DRA thread.

If no TCBs are available, the DRA either creates a new thread TCB (until the maximum number of threads as specified by the MAXTHRD parameter in the INIT request is reached), or makes the SCHED request wait until a thread becomes available.

The value in the PAPLWCMD field indicates whether the thread to which the SCHED request applies is a short or long thread. The type of thread determines the action that IMS takes when a database command is entered for a database scheduled to the thread. The /STOP DATABASE, /DBDUMP DATABASE, or /DBRECOVERY DATABASE command issued against a database scheduled on a short thread will wait for the database to be unscheduled. IMS rejects these commands if they are entered for a database scheduled on a long thread.

You must fill in the following input fields in the PAPL:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLFUNC</td>
<td>PAPLTFUN, thread function code</td>
</tr>
<tr>
<td>PAPLSFNC</td>
<td>PAPLSCHE, schedule request subfunction code</td>
</tr>
<tr>
<td>PAPLCTOK</td>
<td>The DRA request token (output from an INIT request)</td>
</tr>
<tr>
<td>PAPLTTOK</td>
<td>The thread token set up by the CCTL</td>
</tr>
<tr>
<td>PAPLRTOK</td>
<td>The 16-byte UOR token (RTOKEN).</td>
</tr>
</tbody>
</table>
The first 8 bytes contain the CCTL identification. This identification is the same as the CCTL ID that was a final DRA startup parameter determined from USERID or PAPLUSID in INIT request; the USERID parameter is found in the DFSPRP macro used to generate the DFSPZPxx module. The second 8 bytes contain the unique identifier specified by the CCTL for each UOR.

**PAPLPSB**

The PSB name

**PAPLWRTH**

Deadlock Worth Value

If this thread hits a deadlock condition with any other DRA thread or with any IMS region, DBCTL collapses the thread with the lower deadlock worth value.

**PAPLWCMD**

This bit defines the thread as either a short or long thread which determines what action IMS takes on a /STOP DATABASE, /DBDUMP DATABASE, or /DBRECOVERY DATABASE command for a database scheduled to the thread.

If the bit is set on (X'80'), the database is scheduled on a short thread; if the bit is set off, the database is scheduled for a long thread.

**PAPLFTRD**

Fast Path Trace Option

If this bit is on (X'40'), Fast Path tracing in IMS DB is activated.

**PAPLKEYP**

Public Key Option

If this bit is set (X'10'), DBCTL builds UPSTOR area in a special subpool so that applications running in public key can fetch the UPSTOR area.

**PAPLLKGV**

Lockmax Option

If this bit is set (X'08'), DBCTL uses the value in PAPLLKMX as the maximum number of locks that this UOR can hold. Exceeding the maximum results in a U3301 abend.

**PAPLLKMX**

Lockmax Value, 0 to 255

This value overrides any LOCKMAX parameter specified on the PSBGEN for the PSB referenced in the SCHED request.

**PALPUFXT**

DRA open thread indicator.

Set PALPUFXT to 1 for the SCHED call to indicate to the DRA that the thread TCB might not be the same TCB for the duration of the thread. The TCB might change between the time that the PSB is scheduled and the time that the PSB is unscheduled and the thread is terminated.

**PAPLALAN**

Application language type

Specifying the following input field is optional:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
</table>
PAPLSTAT
Address of an area where scheduled statistical data is returned to the CCTL.
If you do not want to allocate an address, enter 0.

PAPLPBTMK
Address of the token for the z/OS Workload Manager performance block obtained by the CCTL.
You must specify this field for z/OS Workload Manager support for DRA threads.

PAPLTECB
To use the default Suspend exit routine and Resume exit routine, each DRA request must have the field PAPLTECB set with the address of a CCTL ECB to be used if the thread is waited or posted. If your CCTL does not provide Suspend and Resume exit routines, the DRA default exit routines will be used.

The output fields returned in the PAPL to the CCTL are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLRETC</td>
<td>The return code</td>
</tr>
<tr>
<td>PAPLCTK2</td>
<td>The thread request token number 2. This is another DRA token required on future DRA requests originating from this thread.</td>
</tr>
<tr>
<td>PAPLPCBL</td>
<td>The address of the PCB list. There is one entry in the list for each PCB in the PSB that was scheduled, even if the PCB cannot be used with IMS DB. The address of the PCB list is above the 16 MB line if either the PCBLOC=31 is set on the DFSRPRP macro, or PAPLLPSO=31 is specified on the INIT request.</td>
</tr>
<tr>
<td>PAPL1PCB</td>
<td>The address of the PCBLIST entry pointing to the first database PCB</td>
</tr>
<tr>
<td>PAPLiosz</td>
<td>The size of the maximum I/O area</td>
</tr>
<tr>
<td>PAPLplan</td>
<td>The language type of the PSB</td>
</tr>
<tr>
<td>PAPLMKEY</td>
<td>The maximum key length</td>
</tr>
<tr>
<td>PAPLSTAT</td>
<td>The address of the schedule statistical data area. This address must be specified on the input field.</td>
</tr>
</tbody>
</table>

CCTLs currently using the IMS Database Manager and migrating to DBCTL will experience a change in the PCBLIST and user PCB area on a schedule request. The first PCB pointer in the PCBLIST contains the address of an I/O PCB. The I/O PCB is internally allocated during the schedule process in a DBCTL environment. The I/O PCB is normally used for output messages or to request control type functions to be processed. The PCBLIST and the PCBs reside in a contiguous
storage area known as UPSTOR. If the PSB was generated with LANG=PLI, the PCBLIST points to pointers for the PCBs. If LANG= was not PLI, the PCBLIST points to the PCBs directly.

<tr>
<td></td>
<td>output from a SCHED request.</td>
</tr>
<tr>
<td>PAPLTTOK</td>
<td>Thread token set up by the CCTL</td>
</tr>
<tr>
<td>PAPLRTOK</td>
<td>RTOKEN</td>
</tr>
<tr>
<td></td>
<td>A 16-byte UOR token.</td>
</tr>
<tr>
<td>PAPLCLST</td>
<td>The address of an IMS call list.</td>
</tr>
<tr>
<td>PAPLALAN</td>
<td>Application language type. This must reflect how the call list is set up.</td>
</tr>
<tr>
<td></td>
<td>If PAPLPLAN=’PLI’, the DRA expects the call list to contain pointers to</td>
</tr>
<tr>
<td></td>
<td>the PCB’s pointers. For any other programming language, the DRA expects</td>
</tr>
<tr>
<td></td>
<td>direct pointers.</td>
</tr>
<tr>
<td></td>
<td>PAPLPLAN does not have to match PAPLPLAN which schedules request returns.</td>
</tr>
<tr>
<td></td>
<td>For example, if PAPLPLAN=PLI, the PCBLIST in UPSTOR points to an indirect</td>
</tr>
<tr>
<td></td>
<td>list. If specified, the CCTL can use this to create a PCBLIST that</td>
</tr>
<tr>
<td></td>
<td>application programs use. If the application programs are written in</td>
</tr>
<tr>
<td></td>
<td>COBOL, the CCTL may create a new PCBLIST without pointers as long as the</td>
</tr>
<tr>
<td></td>
<td>new list actually points to PCBs in UPSTOR. The application program</td>
</tr>
<tr>
<td></td>
<td>IMS call lists can specify PAPLPLAN=COBOL, and the DRA will not</td>
</tr>
<tr>
<td></td>
<td>expect pointers in the call list.</td>
</tr>
</tbody>
</table>

In addition to the required input parameters, the optional input parameters include:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
</table>

Chapter 22. CCTL-initiated DRA function requests
To use the default Suspend exit routine and Resume exit routine, each DRA request must have the field PAPLTECB set with the address of a CCTL ECB to be used if the thread is waited or posted. If your CCTL does not provide Suspend and Resume exit routines, the DRA default exit routines will be used.

The output fields returned in the PAPL to the CCTL are:

<table>
<thead>
<tr>
<th>Field</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAPLRETC</td>
<td>Code returned</td>
</tr>
<tr>
<td>PAPLSEGL</td>
<td>Length of data returned</td>
</tr>
</tbody>
</table>

<tbody>
<tr>
<td><strong>PAPLRETC</strong></td>
<td>Code returned</td>
</tr>
<tr>
<td><strong>PAPLSTAT</strong></td>
<td>The address of the transaction statistical data area. This address must be specified on the input field.</td>
</tr>
</tbody>
</table>
Chapter 23. Terminating the DRA

Termination isolation means that a failure of the IMS DB subsystem does not cause a direct failure of any attached CCTL subsystem or ODBA application and vice versa.

Termination isolation should be one of your primary considerations when you design a CCTL subsystem or an ODBA application.

Although IMS DB was designed to prevent failure between connecting subsystems, a termination of a CCTL subsystem can cause IMS DB failure. If a DRA thread TCB terminates while IMS DB is processing a thread DL/I call on the CCTL’s behalf, IMS DB fails with a U0113 abend.

The conditions that cause a thread TCB to terminate while IMS DB processes a DL/I call are:

- A DRA thread abend due to code failure. This can be corrected by fixing the failing code.
- The CCTL TCB collapses while a thread TCB still exists. The thread TCB collapses with an S13E or S33E abend and can result from three situations: a CCTL abend, a cancel command, or a shutdown.
- A DRA thread abend due to a IMS DB /STOP REGION CANCEL command initiated by CCTL.

An IMS DB U0113 abend can be prevented by designing the CCTL recovery process so that it issues a TERM request and waits for the request to complete. This allows the DRA and thread TCBs to terminate before the CCTL TCB terminates.

Related concepts:

[Chapter 24, “Designing the CCTL recovery process,” on page 349]
Chapter 24. Designing the CCTL recovery process

You should consider CCTL operations and installation requirements when designing your CCTL. For example, a CCTL might have a means of allowing its own shutdown, but CCTL threads or BMPs should not have long-running UORs.

Under the conditions of a nonrecoverable z/OS abend, a DRA TERM request lets all threads collapse and U0113 is possible. To reduce the number of nonrecoverable abends of the CCTL, IMS DB intercepts any operator CANCEL of a CCTL that is connected to IMS DB, and converts it to a S08E recoverable abend of the CCTL. If you want a CANCEL to be converted to an S08E abend, you must specify CCTCVCAN=Y on IMS startup parameters.

You can also as a last resort, force a CCTL to shut down. If an operator enters a FORCE command after CANCEL has been entered (and converted to S08E), IMS DB converts FORCE into a z/OS cancel command. Subsequent FORCE attempts are not intercepted by IMS DB. In these cases of nonrecoverable abends, a U0113 is possible.

A CCTL might have a means of allowing its own shutdown. The CCTL shutdown logic should issue a DRA TERM request and wait for the request completion to prevent a U0113 abend in IMS DB. The DRA TERM request waits for current thread requests to complete. One thing that can prevent a current thread DL/I call from completing normally is if the call has to wait in IMS DB for a database segment to become available. The reason the segment might not be available is that it is held by another UOR, either in a thread belonging to another CCTL or in an IMS dependent region (for example, a BMP). The solution is to not have CCTL threads or BMPs that have long-running UORs.

**Recommendation:** BMPs should take frequent checkpoints.

No matter how you choose to prevent or discourage long-running CCTL threads, you must decide how long to wait for the DRA TERM request to complete (TIMEOUT). In most cases, it is undesirable to get a U113 abend in IMS DB during a CCTL termination, so the timeout value should be greater than the longest possible UOR. If the CCTL has a means of limiting the UOR time or allowing the installation to specify this time limit, the DRA TERM timeout value can be determined. This timeout value can be specified in the DRA startup table and is returned to the CCTL in the INIT PAPL.

**Recommendation:** CCTL should use this DRA TERM timeout value when waiting for the DRA TERM request to complete. At the very least, by using the DRA TERM timeout value, you can control whether CCTL terminations cause IMS DB failures with respect to the UOR time length of the applications that run in a given IMS DB/CCTL session.

CCTL Operations Recommendation:
- Avoid using CANCEL or FORCE commands against CCTL regions that are connected to IMS DB.

CCTL Design Recommendations:
• The CCTL should issue a DRA TERM request during recoverable abend processing.
• CCTL shutdown functions should issue a DRA TERM request.
• Whenever a DRA TERM request is issued, wait for it to complete. If this time must have an upper limit, use the TIMEOUT value specified in the DRA startup table.
• The CCTL should prevent long-running UORs in its threads using IMS DB.

User Installation Recommendations:
• Have BMPs take frequent checkpoints.
• Limit long-running UOR applications.
• Set the TIMEOUT startup parameter as high as possible, preferably longer than the longest running UOR.

Related concepts:
Chapter 23, “Terminating the DRA,” on page 347
Chapter 25. CCTL performance: monitoring DRA thread TCBs

You can evaluate the status of DRA thread TCBs from the output of the /DISPLAY CCTL ALL command in most cases. If there are no thread failures, the output might show fewer thread TCBs than the MINTHRD value because of internal short lived conditions.

**Requirement:** The DRA initialization process requires a minimum and maximum value (MINTHRD and MAXTHRD) for DRA thread TCBs. The value of MINTHRD and MAXTHRD determine the number of multithreading executions that can occur concurrently. These values also define the range of thread TCBs that the DRA will maintain under normal conditions with no thread failures. The number of TCBs can go below the MINTHRD value when the following thread failures occur:

- An abend.
- A nonzero DRA thread request return code that causes the thread TCB to collapse.
- Termination using a IMS DB /STOP REGION command.

Failed thread TCBs are not automatically recreated. The thread TCB number increases again if a new thread is created to process a SCHED request. If the number of thread TCBs is greater than the MINTHRD value and all thread activity ceases normally, the number of thread TCBs left in the DRA will be the MINTHRDD value.

During CCTL processing, the number of active DRA threads occupying thread TCBs varies from 0 to the MAXTHRD number. Active DRA threads indicate that at least one SCHED request has been made but not any TERMTHRD requests. If the number of non-active thread TCBs becomes too large, the DRA automatically collapses some thread TCBs to release IMS DB resources.

The status of DRA thread TCBs can be evaluated from the output of the /DISPLAY CCTL ALL command, except for one case.

If there were no thread failures, the output might show fewer thread TCBs than the MINTHRD value because of internal short lived conditions. In fact, the actual number of thread TCBs equals the MINTHRD.

### DRA thread statistics

DRA thread statistics are returned for a SCHED request and for any DRA requests that terminate a UOR. The statistics are in a CCTL area that is pointed to by the PAPLSTAT field.

The PAPL listing maps this area, as shown in the following table. The statistics also appear in the IMS DB log records X'08' (SCHED) and X'07' (UOR terminate).

DRA statistics

DRA statistics are contained in the returned PAPL as a result of a DRA TERM request, or in the Control exit routine’s PAPL when it is called for DRA termination. This routine is called when the DRA fails or when a previous Control exit routine invocation resulted in return code 4.

The DRA statistics in the returned PAPL are:
1. The number of times the MAXTHRD value was reached.
2. The number of times the MINTHRD value was reached (only includes the times the value is reached when the thread TCB number is decreasing.)
3. The largest number of thread TCBs ever reached during this DRA session. (This is the number of TCBs, not the number of DRA threads, so it is at least the minimum thread value.)
4. The time (in seconds) during which the DRA thread TCB count was at the MAXTHRD value.

You can find the field names for the previous statistics in the PAPL extensions for the TERM PAPL and control exit routine PAPL.

Before attempting to evaluate the statistics DRA performance, remember:
- If the DRA is using the maximum number of threads (MAXTHRD), when the DRA receives any new SCHED requests it will make these requests wait until a thread is available.
- As active threads become available (for example, as a result of TERMTHRD call), some of the available threads might be collapsed.

These factors can adversely affect performance, but both improve IMS DB resource availability because fewer DRA threads require fewer IMS DB resources. The IMS DB resources (PSTs) are then available for other BMPs or other CCTLs to use.

Statistics 1, 2, and 4 can serve as a measurement of the two factors, and will help you decide how to balance performance and resource usage. For the sake of this discussion, these statistics are presented solely from a performance point of view (for example, assume only 1 CCTL connected to a IMS DB).

Evaluating the DRA statistics

If statistics 1 and 4 are high, a SCHED request had to wait for an available thread many times. To improve performance, raise the MAXTHRD value.

The impact of statistic 2 on performance can only be estimated if thread activity history is known (the DRA does not provide this history but the CCTL can). If activity is steady, little thread collapsing occurs and statistic 2 is meaningless. If activity fluctuates a lot, statistic 2 can be useful.
• If statistic 2 is 0, thread collapsing might have occurred, but the MINTHRD value was never reached.

• If statistic 2 is not zero, the MINTHRD value was reached and thread collapsing was stopped at those points, thus enhancing performance. Therefore, if you have highly fluctuating thread activity, you can improve performance by raising MINTHRD until statistic 2 has a nonzero value.

Finally, statistic 3 can be useful for adjusting your MAXTHRD value.

Note: These statistics are useful in determining MINTHRD and MAXTHRD definitions. When MINTHRD=MAXTHRD, these statistics are of no value.

DRA tracing

Tracing (logging) of activity does not occur in the DRA, but there is tracing in IMS DB of DL/I and Fast Path activity. The setup and invocation of DL/I tracing for IMS DB is the same as for IMS. The output trace records for CCTL threads contain the recovery token.

Fast Path tracing in IMS DB is different from IMS. Fast Path tracing in IMS DB is activated when a SCHED request to the DRA has the PAPLFTRD equal to ON (Fast Path trace desired for this UOR).

When this UOR completes, a trace output file is closed and sent to SYSOUT Class A.

If a thread request fails during Fast Path processing, the DRA might return the PAPL with the PAPLFTRR field equal to ON. This recommends to the CCTL that it request the PAPLFTRD field be equal to ON (Fast Path trace desired) in the SCHED PAPL if this failing transaction is run again by the CCTL.

Related reference:
"SCHED request" on page 338

Sending commands to IMS DB

In an IMS DB warm standby or IMS XRF environment, a CCTL can use a z/OS SVC 34 to broadcast an emergency restart command to an IMS DB alternate, or a SWITCH command to an IMS XRF alternate in order to have the IMS alternate system become the primary IMS system.

These are the only IMS commands that can be done using this interface. The command verb can be preceded by either the command recognition character or the 4-character IMS identification that is in the PAPLDBCT field of the INIT PAPL.

Problem diagnosis

Diagnostic information is provided by the DRA in the form of an SDUMP, or a SNAP data set output. For X'80', the SDUMP is attempted first. If it fails, SNAP is done.

Failed DRA requests have a nonzero value in the PAPLRETC field of the PAPL returned to the CCTL. The format of PAPLRETC is:
HHHSSUUUU

Where: HH= X'00'- No output

354 System Programming APIs
**UUU** IMS DB return codes

X'88'- No output

**SSS** All z/OS non-retrievable abend codes (for example, 222, 13E) or,

**UUU** IMS abend codes (775, 777, 844, 849, 2478, 2479, 3303)

X'84'- SNAP only

**UUU** IMS abend codes (260, 261, 263)

X'80'- SDUMP/SNAP provided

**SSS** All the z/OS abend codes that can be tried again

**UUU** All IMS abend codes besides those that are listed for the format of
PAPLRETC

Diagnostic information is provided by the DRA in the form of an SDUMP, or a
SNAP data set output. For X'80', the SDUMP is attempted first. If it fails, SNAP is
done. For X'84', no SDUMP is attempted, but a SNAP is attempted.

A z/OS or IMS abend code failure results in DRA thread termination and thread
TCB collapse. An IMS DB return code has no affect on the DRA itself or the thread
TCB.

DRA thread TCB failures that occur when not processing a thread request result in
a SDUMP/SNAP process. DRA control TCB failures that occur when not
processing a DRA request result in a SDUMP/SNAP process and the Control exit
routine is called. For a thread request of type SCHED, a failure with X'80' or X'84'
can result in either SNAP or SDUMP.

**SDUMP**

SDUMP output contains:

- The IMS control region.
- DLISAS address space.
- Key 0 and key 7 CSA.
- Selected parts of DRA private storage, including the address space control block
  (ASCB), task control block (TCB), and request blocks (RBs).

You can format the IMS control blocks by using the Offline Dump Formatter
(ODF).

The ODF will not format DRA storage. You can use IPCS to format the z/OS
blocks in CCTL private storage.

DRA SDUMPS have their own SDUMP options. As a result, any CHNGDUMP
specifications cannot cause sections of DRA SDUMPs to be omitted. If these
specifications are not in the DRA list of options, they can have an additive effect
on DRA SDUMPS.

**SNAP**

The SNAP dump data sets are dynamically allocated whenever a SNAP dump is
needed. A parameter in the DRA Startup Table defines the SYSOUT class.
The SNAP output contains:

- Selected parts of DRA private storage, including the ASCB, TCB, and RBs.
- IMS DB control blocks.

[Related information](https://www.example.com)
Part 5. Database Recovery Control (DBRC)

You can use DBRC to record and manage information that is stored in a set of VSAM data sets that are collectively called the REcovery CONtrol (RECON) data set. Based on this information, you can use DBRC to advise IMS about how to proceed for certain IMS actions.
Chapter 26. DBRC API

Your applications can obtain services from Database Recovery Control (DBRC) through the DBRC application programming interface (API), a release-independent, assembler macro interface. The application obtains these services by issuing DBRC API requests to DBRC, and DBRC returns the results to an area in storage where the application can retrieve them.

The DBRC API is provided with IMS in the DSPAPI macro. A sample application program (DSPAPSMMP) that uses the DBRC API is included in the IMS.ADFSSMPL (also known as IMS.SDFSSMPL) library.

Important: All DBRC API requests must be issued under the same TCB where the DBRC start request (STARTDBRC) was issued. Any request that is issued under a different TCB fails with reason code XC900000A.

To write a program that uses the DBRC API, you must have a working knowledge of:
- Assembler language programming
- z/OS and the services it supplies
- IMS
- DBRC

Related concepts:

- “Database query request (TYPE=DB)” on page 390
- “DBDS query request (TYPE=DBDS)” on page 412

Structure of applications that access the DBRC API

Your applications must follow a general structure in order to access the DBRC API.

The general structure of an application that uses the DBRC API is as follows:
1. Include the API DSECTS (DSPAPI FUNC=DSECT)
2. Initialize the API, start DBRC, establish a connection to the RECON data sets, and receive the API token (DSPAPI FUNC=STARTDBRC)
3. Issue one or more Query requests (DSPAPI FUNC=QUERY)
4. Process the information that is returned from the Query requests
5. Return buffer storage (DSPAPI FUNC=RELBUF)
6. Terminate DBRC and the DBRC API (DSPAPI FUNC=STOPDBRC)

How an application program establishes the DBRC API environment

Your application program establishes the application programming interface (API) environment by using the DSPAPI FUNC=STARTDBRC macro. This macro function initializes the API, creates a connection to the Database Recovery Control (DBRC) RECON data sets, and returns the API token.

Requirements:
- The API token must be specified for all subsequent API calls.
- All API requests must be issued under the same task control block (TCB) where the FUNC=STARTDBRC was issued.

Related concepts:
“The DBRC API token” on page 362

How an application program ends the DBRC API environment

After it has completed its work with DBRC, your application program must end the API environment using the DSPAPI FUNC=STOPDBRC macro. This macro function allows DBRC to terminate, deallocates any data sets that DBRC had allocated, and frees storage allocated to the API environment.

Addressing and residency mode

Your application must invoke the DBRC API in 31-bit addressing mode and can reside either above or below the 16 MB line.

Parameter addresses passed to the API can be above or below the 16 MB line unless otherwise stated in a macro description. Parameter addresses returned to the user by the API likewise can be above or below the 16 MB line.

Address space control (ASC) mode and state

Your application must be in primary ASC mode to invoke the API services.

Cross memory mode is not supported. The application can run in either problem program state or supervisor state, and can also run as an APF authorized program.

How the DBRC API uses registers

General purpose registers 0, 1, 14, and 15 can be changed by the DBRC API. Register 13 must contain the address of a standard (18 word) save area. The contents of registers 2-13 are unchanged by the DBRC API.

How to include equate (EQU) statements in your DBRC API application

You can use the DSECT function of a DSPAPI request to include equate (EQU) statements and constants used by the DSPAPI macro in your program.

The following syntax is for the DSECT function of a DSPAPI request.

```
DSPAPI-FUNC=DSECT
```
API application

Parameters that are specified on the DSPAPI macro are either literals, addresses, or values. You can pass an address or a parameter value by using a register, a symbol, or a literal. You can specify literal values in mixed case.

Use a register
To use a register, you must load the address of a symbol or value into one of the general purpose registers, and then use that register (enclosed in parentheses) for the parameter in the DSPAPI request. Use only registers in the range 2-12. Register notation does not work with MF=L because this form does not produce executable code.

The following example shows how to pass an address using a register:

```
LA 5,OUTPUTAD
dspapi func=query, output=(5), ...
```

OUTPUTAD DS A

The previous example generates the following instruction:

```
ST 5,DSPAPI_Plist_Output
```

Use a symbol name
To use a symbol name, you must define a named area of storage that either contains the desired value, or will receive a returned address or value, and then use that symbol name for the parameter in the DSPAPI request.

The following example shows how to pass an address using a symbol name:

```
dspapi func=query, output=OUTPUTAD, ...
```

OUTPUTAD DS A

The previous example generates the following instructions:

```
la 0,OUTPUTAD
st 0,DSPAPI_Plist_Output
```

Use a literal
You can use literals for certain parameter values, such as time stamps. To use a literal, pass the literal as a hexadecimal string for the parameter in the DSPAPI request. Literals can also be mixed-case.

The following example shows how to pass a value using a literal:

```
dspapi func=query, type=log, c
    starttime="XL12'1980030F191212009999028D"
```

The previous example generates the following instructions:

```
la 0,'XL12'1980030F191212009999028D'
st 0,DSPAPI_Plist_Startime
```

Unless specifically noted, name fields are 8 characters long, left justified, and padded with blanks.
Versions of the DBRC API macro

Because parameter lists can change from one release of IMS to the next, the functions provided by the DSPAPI macro have a version associated with them. You must specify that version number or a later version to use the functions or parameters that are associated with a version.

If parameters have a version dependency, the parameter descriptions in each request type identify the minimum version number that is required.

The output block version number of the DBRC API is:

- 5.0 for IMS Version 13
- 4.0 for IMS Version 12
- 3.0 for IMS Version 11

The DBRC API token

The DBRC API token is a 4 byte field that is used to relate a series of API requests.

Your program receives this token when a DSPAPI FUNC=STARTDBRC macro is issued. This token must be supplied with all other macro calls that are associated with this instance of the STARTDBRC macro. The token is no longer valid after a DSPAPI FUNC=STOPDBRC macro call. Your program does not receive a token if the macro encounters a severe error (return code X’0000000C’). If the function receives a warning error (return code X’00000004’), find the meaning of the accompanying reason code in Chapter 32, “DBRC start request (STARTDBRC),” on page 459 to determine what action is needed.

Related concepts:

“How an application program establishes the DBRC API environment” on page 360

Macro forms of the DSPAPI macro

There are four different macro forms for the DSPAPI macro: Standard (S), List (L), Modify (M), and Execute (E), with two variations, COMPLETE and NOCHECK. The List, Modify, and Execute forms are usually used in combinations when writing reentrant programs or when the application issues multiple requests.

Defaults are taken where necessary and less validity checking is performed than for the Standard Form. The following are explanations about when and why to use each form.

Standard form (default)

Use the standard form of the macro (MF=S or MF=S,list) to generate and modify an inline parameter list. If your program is reentrant, do not use the standard form of the macro because reentrant code cannot be modified. With few exceptions, if you use the standard form of the macro in writing reentrant code, the execution of the code results in an abend. The standard form of the macro serves three functions:

- Creates an inline parameter list
- Modifies the parameter list with the parameters specified on the request
- Sends the request to the API

Using the standard form, you can optionally assign a label to the generated parameter list by specifying MF=(S,list) where list specifies the name of the
label assigned to the parameter list created by this form of the macro. The standard MF=S form of the macro is the default.

List form

Use the list form of the macro (MF=L,list) to generate a labeled, inline parameter list. This list is populated with the parameter values specified on the macro. The list form does not modify an existing list and does not send a request to the API. In effect, the list form creates a template that can be used as the target of a modify form or an execute form (the real list you plan to use). If the parameter list is generated in reentrant code, it cannot be modified. Therefore, you must obtain enough storage to hold the parameter list and use this storage as the target of the modify or list form.

list specifies the name of the label assigned to the parameter list created by this form of the macro.

Register notation is not compatible with the List Form of the macro. Instead, an ADCON of zero is generated.

Modify form

Use the modify form of the macro (MF=M,list,COMPLETE | NOCHECK) to change the values specified on the macro in the parameter list specified by the list parameter. The modify form does not generate a parameter list and does not issue requests to DBRC.

list A symbol or a general purpose register in the range 2 to 12 that specifies the address of the parameter list to be modified.

COMPLETE Specifies that DBRC uses defaults (for the parameters that have defaults) for all parameters that are not in the list and performs validity checking for the parameters that are specified in the list.

NOCHECK Specifies no defaults are set and the existing parameter list is used. Validity checking is minimal. However, invalid keyword combinations are flagged in error.

Execute form

Use the Execute form of the macro (MF=E,list,COMPLETE | NOCHECK) to:

• Modify a parameter list (generated by the list form) with new and additional allowable parameters you might not have specified on the List form

• Issue a request to the API

You can change the parameters on the macro with each subsequent invocation of the execute form of the macro.

list Can be a symbol or a general purpose register in the range 2 to 12 and specifies the address of the parameter list to be used.

COMPLETE Specifies that DBRC uses defaults (for the parameters that have defaults) for all parameters that are not in the list, and performs validity checking for the parameters that are specified in the list.

NOCHECK Specifies no defaults are set and the existing parameter list is used. Validity checking is minimal. However, invalid keyword combinations are flagged in error.
The following syntax is a summary of the macro forms:

\[
\text{MF}=S \mid L \mid M \mid E
\]

Specifies the macro form:

\[
\text{MF}=S \mid \text{MF}=(S,\text{list})
\]

Specifies the standard form of the macro. MF=S is the default.

\[
\text{MF}=(L,\text{list})
\]

Specifies the list form of the macro.

\[
\text{MF}=(M,\text{list},\text{COMPLETE}|\text{NOCHECK})
\]

Specifies the modify form of the macro.

\[
\text{MF}=(E,\text{list},\text{COMPLETE}|\text{NOCHECK})
\]

Specifies the execute form of the macro.

Runtime considerations for the DBRC API

There are various considerations that you must address while the DBRC API is running such as DSPAPI and RECON access and how the API operates in an IMSplex.

DSPAPI macro access

In order to provide DBRC API (DSPAPI) macro access, your application must allocate IMS.SDFSRESL as either a JOBLIB or STEPLIB in your program’s JCL because the DSPAPI is distributed with IMS.

RECON data set access

While the DBRC API is running, it uses up to three RECON data sets, which are allocated using the DD names RECON1, RECON2, and RECON3, or their respective alternate DD names. MDA members must be created for the data sets before the DBRC API can allocate RECONs.

The RECONs can be allocated:
- Dynamically by the API when the DSPAPI FUNC=STARTDBRC request is issued–this is the recommended method
- Dynamically by your application program
- Through your JCL

If the DBRC API allocates the RECONs, they are deallocated when the DSPAPI FUNC=STOPDBRC request is issued. Before the DBRC API can allocate the RECONs, MDA members must have been created for RECON1, RECON2, and RECON3. or their respective alternate DD names. The MDA members must exist either in a library allocated as //IMSDALIB, or in the //JOBLIB or //STEPLIB libraries. The DBRC API first searches in //IMSDALIB, if it exists, for the MDA members.

The IMS libraries concatenated to JOBLIB or STEPLIB are usually APF Authorized. If your program runs APF Authorized and the library containing the MDA members is not APF Authorized, allocate it using IMSDALIB as the DD name.

Requirement: All jobs accessing a set of RECON data sets must allocate the same data set by the same DD name. For example, RECON1=dsn1, RECON2=dsn2, and RECON3=dsn3. Failure to follow this convention causes serious damage to the RECONs.
The API uses only one set of RECONs between a FUNC=STARTDBRC request and its associated FUNC=STOPDBRC request. Your program, however, can use multiple sets of RECONs by deallocating the RECONs after the FUNC=STOPDBRC request and then allocating a new set of RECONs before issuing the next FUNC=STARTDBRC request. In order for this to work, your program must dynamically allocate the RECONs.

Related reference:

DFSMDA macro (System Definition)

RECON access authority

You can set three levels of access control for DBRC. Each level provides different permissions to users that access the RECON data sets.

DBRC allows three levels of access control:

- Users who delete and define information in the RECON data sets require ALTER authority.
- Users who only update the RECON data sets require UPDATE authority.
- Users who do not update the RECON data sets, but who want to query information from the RECON data sets, require READ authority.

The READONLY keyword for the DBRC Start API request (STARTDBRC) allows a user to specify a READONLY option. READONLY is also a JCL EXEC PARM on the Database Recovery Control utility (DSPURX00). READONLY specifies that the job is not allowed to make any updates to the RECON data sets. READONLY is necessary if the user submitting the job does not have UPDATE (or higher) authority for the data sets. When READONLY is specified, there is no recovery action taken when an error occurs on a RECON data set. Instead of swapping in a spare data set, the job is terminated.

Time stamp format for DBRC requests

Time stamps that are associated with DBRC requests (either input or output) follow a packed decimal UTC time format. DBRC ignores the value of the offset field in time stamps that are provided on Query requests.

The time stamp is in the following format:

yyyydddFhhmmstfhmijufqqs

Where:

- **yyyy** year (0000 to 9999)
- **ddd** day (000 to 366)
- **F** Hexadecimal character for padding purposes (X’F’)
- **hh** hour (0 to 23)
- **mm** minute (0 to 59)
- **ss** second (0 to 59)
- **thmiju** millionths of a second (microseconds, 000000 to 999999)
- **fqqq** Time zone offset:
  - **f** Flag bits, normally 0 for UTC representation
  - **qqq** Quarter hours (32/4=8)
  - **s** Sign (D is negative, C is positive)
How DBRC uses the output data set

While running under the DBRC API, DBRC might output messages and other information to a data set defined by the DD name SYSPRINT, or by a DD name you specify. If your program already uses the DD name SYSPRINT, you can specify an alternate DD name for the API to use.

This output data set might be on tape, DASD, a printer, or routed through the output stream (SYSOUT). The data set might be allocated by your program through JCL or dynamically allocated prior to invoking the DBRC API. The attributes for this data set are RECFM=FBA, LRECL=121. Do not specify the block size because DBRC will use a system determined block size (the system determines an optimal blocksize for the device).

Wildcard support for name parameters for Query requests

For more flexible Query requests, you can use a wildcard (an asterisk) in several keyword parameters that specify names. This wildcard support enables you to specify a name pattern for your query, expanding some queries and filtering others.

The asterisk can be used in two formats:

- Use the asterisk alone to request information for all DB names, groups, or subsystems, depending on the query type.
- Use the asterisk at the end of a name to request information for DB names, groups, or subsystems whose names match the patterns. In this case, the asterisk must be preceded by at least one alphabetic character.

Use of wildcards is supported in the following parameters:

Table 84. Parameters for DBRC QUERY with wildcard support

Chapter 28. DBRC authorization request (AUTH)

You can use the DBRC authorization request to ensure that an invalid data sharing environment is not created. Database authorization is the process of requesting permission to access and use a database. In this context, the database is either a DL/I database or a Fast Path DEDB area.

The type of access requested can be:

- Exclusive (EX) control of the resource. Exclusive access is granted if the database is not currently authorized. After access is granted, any and all other authorization requests are not allowed. This type of authorization is used typically by a recovery utility.

- Read (RD) access to the database (also called read with integrity). Read access is granted if the database is not currently authorized as exclusive or update. After this access is granted, other authorization request for exclusive or update fails. This type of authorization is typically used by utilities that take non-concurrent (clean) image copies.

- Read-only (RO) access to the database (also called dirty read). Read-only access is granted unless the database is currently authorized as exclusive. Once granted, other authorization request for exclusive fail. Read-only access does not prevent the database from being updated while the application is reading it. This type of access is typically used by utilities that take concurrent image copies.

An application must register with DBRC when it initializes in order to use this function. The requested database must be registered with DBRC.

The database is unauthorized explicitly by the DSPAPI FUNC=UNAUTH macro, or implicitly by the DSPAPI FUNC=STOPDBRC macro.

You can specify one or more database names for the authorization and unauthorization functions. Databases do not have to be unauthorized in the same order that they are authorized. For instance, if multiple databases in a list are authorized, they can be unauthorized one at a time in any order. To change the type of access, unauthorize the database and then authorize the database again.

There are some situations in which standard database authorization is denied, such as when the "Prohibit Authorization" flag is on for a database, or if one or more of its DBDSs require an image copy. If the intent of the application is database image copy, recovery or reorganization, you can grant the authorization by using the UTILITY keyword on the FUNC=AUTH request.

Syntax for the AUTH request

You can use this syntax diagram to understand the format of the DBRC AUTH request.
Parameters for the AUTH request

You can use this information to understand the parameters for the DBRC AUTH request. Each parameter is explained as it relates to the AUTH request syntax diagram.

**name**
Begin the name in column 1.

**TOKEN=address | (2-12)**
Specifies the address of the API token that was returned on the FUNC=STARTDBRC macro.

**AUTHLIST=name | (2 - 12)**
Specifies the list of database names or Fast Path areas to be authorized. The list consists of a fullword that contains the number of elements in the list, a fullword that contains the length of an element, followed by one or more elements. Each element consists of an 8-character DB name or Fast Path DEDB name and 8 characters of blanks (X'40') or a Fast Path area name.

**ACCESS=EX | RD | RO**
Specifies exclusive (EX), read (RD) or read-only (RO) authorization is requested. The default is EX.

**OUTPUT=output | (2 - 12)**
Specifies a field to receive a pointer to the authorization output block DSPAPAUB.

The output address is 0 if no output was built. This can happen if nothing in the RECON data set satisfies the request or if an error occurs before any output could be built.

The storage for the output blocks is not preallocated by the caller. DBRC acquires storage from the specified subpool for these blocks. The caller must free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) specifying the returned output address.
SUBPOOL= 0 | number
Specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

UTILITY=IC | RECOV | REORG | NONE
Specifies the intended utility function of the application. The functions include image copy (IC), database recovery (RECOV), database reorganization (REORG), or NONE. The default is NONE, indicating a normal database authorization request.

RETCODE=return code | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reason code | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNCODE is specified, register 0 contains the reason code.

MF=S | L | M | E
Specifies the macro form of the request.

VERSION=2.0 | number
Specifies the version number of the parameter list to be generated by this macro.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

The valid version number for the FUNC=AUTH request is 2.0 (the default).

**AUTH output block mapping**

You can use this figure to understand the format of the output from a TYPE=AUTH request. The output block for the TYPE=AUTH request begins with a standard header that is mapped by the DSPAPQHD. The data portion of this output block is mapped by DSPAPAUB.
The following figure illustrates the format of the output from a TYPE=AUTH.

![Figure 11. Format for a TYPE=AUTH output](image)

**AUTH output block**

This example contains the output block that is returned by the AUTH request. The output block contains an array of authorized databases and indicates if the AUTH request was successful.

“Parameters for the AUTH request” on page 372
Chapter 29. DBRC command request (COMMAND)

You can use the DSPAPI FUNC=COMMAND request to issue a DBRC utility command from your application program. All DBRC commands are accepted on this request, except for the LIST command.

All output generated by the DBRC command request is returned in an API output block rather than sent to SYSPRINT. If DBRC command authorization is enabled, commands entered through the API are produce the same results as the commands executed through the DBRC utility. An IMS DD statement might be required. If GENJCL commands are executed, both a JCLPDS DD statement (or the DD name you supply with the JCLPDS parameter) and a JCLOUT DD statement (or the DD name you supply with the JCLOUT parameter) are required.

Chapter 26, “DBRC API,” on page 359

Syntax for the COMMAND request

You can use this syntax diagram to understand the format of the Database Recovery Control (DBRC) COMMAND request.

Parameters for the COMMAND request

You can use this information to understand the parameters for the DBRC COMMAND request. Each parameter is explained as it relates to the COMMAND request syntax diagram.

name  Specifies the name parameter. If used, begins in column 1.

COMMAND= symbol  | (2 - 12)
  Specifies the address of a DBRC utility command to execute. The command
consists of a header followed by a DBRC command. The header is a full word that contains the length (in bytes) of the following command. The DBRC command must conform to DBRC command syntax, except that the command cannot be continued. Separators, which are blanks, a comma or a comment, are allowed anywhere in the command where a separator is needed and may validly appear at the beginning of the command.

**TOKEN=** *symbol* | (2 - 12)

Specifies the address of a 4-byte field to receive the API token. This token must be included in all subsequent requests that are associated with this DSPAPI request.

**OUTPUT=** *output* | (2 - 12)

Specifies a field to receive a pointer to the block that contains the information for the command.

**SUPPRESS=** | NO | YES

Specifies whether or not the command output is to be returned. SUPPRESS=YES indicates that command output is to be returned only if the command does not complete successfully (return code is not zero). SUPPRESS=NO indicates that command output is always returned. SUPPRESS=NO is the default.

**BUFFERLENGTH=** 4096 | *number* | (2 - 12)

Specifies the length of a buffer to receive the output that is generated by executing the command. If a register is specified, the register must contain the desired length. The maximum length allowed is 32760. If necessary, the length is rounded up to a double-word boundary. The default and minimum value is 4096.

**SUBPOOL=** 0 | *number*

Specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

**RETCODE=** *return code* | (2-12)

If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.

**RSNCODE=** *reason code* | (2-12)

If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNCODE is specified, register 0 contains the reason code.

**MF=** S | L | M | E

Specifies the macro form of the request.

**VERSION=** 2.0 | *number*

Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted for processing and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.
The default version is 2.0.

**Related reference:**

“DBDS query request (TYPE=DBDS)” on page 412
Chapter 30. DBRC query request (QUERY)

You can use the DBRC Query request (DSPAPI FUNC=QUERY) along with the TYPE parameter to retrieve various types of information from the RECON data set.

- Backout (TYPE=BACKOUT)
- Database (TYPE=DB) - This variation of QUERY returns database registration and status information for:
  - Full-function databases
  - Fast Path databases
  - HALDB databases
  - DBDS or area information and supporting recovery-related information for each DBDS or area (allocation, image copy, recovery, and reorganization)
- Database partitioning (TYPE=PART)
- DBDS or area information (TYPE=DBDS)
- Group and member information for the following group types:
  - Change Accumulation (TYPE=CAGROUP). CA execution information can also be returned.
  - DBDS (TYPE=DBDGROUP)
  - Database (TYPE=DBGROUP)
  - Recovery (TYPE=RECOVGROUP)
  - Global Service Group (TYPE=GSGROUP)
- Log, Recovery and System Log Data Set (TYPE=LOG)
- Online Log Data Set (TYPE=OLDS)
- RECON status (TYPE=RECON) - This variation of QUERY returns RECON header information, as well as the status of the RECON configuration.
- Subsystem (TYPE=SUBSYS)

Output from query requests are time consistent and access to the RECON data set is restricted during the processing of the request.

If you enable parallel RECON access, then the Query API request returns output as if you specified LIST.xxx STATIC (the RECON data set is not accessible while DBRC processes the Query request).

“OLDS query request (TYPE=OLDS)” on page 435
“RECON status query request (TYPE=RECON)” on page 445
“Subsystem query request (TYPE=SUBSYS)” on page 449
Output from query requests

Requested information is returned to the calling application in a chain of one or more blocks in storage. The pointer to the beginning of this chain is returned in the area specified by the OUTPUT parameter of the Query request.

The storage for these blocks is not preallocated by the calling application. DBRC will acquire private storage for these blocks. It is the responsibility of the calling application to free this storage using the Buffer Release request (DSPAPI FUNC=RELBUF).

Each storage block begins with a standard header mapped by the DSPAPQHD.

Related concepts:
Chapter 26, “DBRC API,” on page 359

Backout query request (TYPE=BACKOUT)

You can use the Backout query (DSPAPI FUNC=QUERY TYPE=BACKOUT) request to retrieve backout information from the RECON data set for a specific subsystem or all subsystems.

Syntax for the TYPE=BACKOUT query request

```
DSPAPI FUNC=QUERY TYPE=BACKOUT TOKEN=address
SSID=* | symbol | symbol* | (2 - 12)
MF=(S,list) | (L,list) | (M,list) | (E,list) | COMPLETE | NOCHECK
OUTPUT=output
SUBPOOL=0 | number
RETCODE=returncode
RSNCODE=reasoncode
VERSION=2.0 | number
```

Parameters for the TYPE=BACKOUT query request

- **name**  If used, begins in column 1.
- **TYPE=BACKOUT**  Specifies that backout information is requested.
- **TOKEN=symbol | (2 - 12)**  Specifies the address of a 4-byte field that was returned on the FUNC=STARTDBRC request.
- **SSID=* | symbol | symbol* | (2 - 12)**  Specifies the subsystem name for the backout being queried. You can use
the wildcard keyword * (an asterisk) alone to request information about all
groups (SSID=*, which is the default). You can also add it at the end of a
name to query all subsystems whose names match the pattern. In this case,
the asterisk must be preceded by at least one alphabetic character.

MF=S | L | M | E
Specifies the macro form of the request.

OUTPUT=|output | (2 - 12)
Required parameter that specifies a field to receive a pointer to the first
block of backout information blocks.

The output address is 0 if no output was built. This can occur if nothing in
the RECON satisfies the request or if an error occurs before any output
could be built.

The storage for the output blocks is not pre-allocated by the caller. DBRC
acquires storage from the specified subpool for these blocks. The caller
must free this storage using the Buffer Release service (DSPAPI
FUNC=RELBUF) and specify the returned output address.

SUBPOOL= | 0 | number
Specifies the subpool number for the storage being obtained. If not
specified, the default is the subpool specified by the FUNC=STARTDBRC
request. Otherwise, subpool 0 is the default.

RETCODE=|returncode | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive
the return code. If specified as a register, the register must contain the
address of a word of storage to receive the return code. Regardless of
whether RETCODE is specified, register 15 contains the return code.

RSNCODE=|reasoncode | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage
to receive the reason code. If specified as a register, the register must
contain the address of a word of storage to receive the reason code.
Regardless of whether RSNCODE is specified, register 0 contains the
reason code.

VERSION=2.0 | number
Specifies the version number of the parameter list that is generated by this
macro.

To use the parameters associated with a version, you must specify the
number of that version or a later version. If you specify an earlier version
level, the parameter is not accepted by macro processing, and an error
message is issued at assembly time. If parameters have a version
dependency, the parameter descriptions with each request type identify the
version number required.

Valid version numbers for the FUNC=QUERY TYPE=BACKOUT request
are 1.0 and 2.0.

</tbody>
</table>

The following structure maps the unit of recovery entries. There is one such entry for each unit of recovery (that is, there are apqbo_UORCOUNT entries). Each unit of recovery entry contains the offset within the backout block to the previous and following entries. Field apqbo_PrevUOR is the offset of the previous entry and apqbo_NextUOR is the offset of the following entry. For the first unit of recovery (UOR) entry, apqbo_PrevUOR will be zero. Similarly, apqbo_NextUOR will be zero for the last entry. Addressability to the first UOR entry is given by:

rfy apqbo_UORentry based(addr(DSPAPQBO) + apqbo_FirstUOR)

Addressability to the last UOR entry is given by:

rfy apqbo_UORentry based(addr(DSPAPQBO) + apqbo_LastUOR)

Addressability to the next UOR entry, if one exists (that is: apqbo_NextUOR not equal to 0), is given by:

rfy apqbo_UORentry based(addr(DSPAPQBO) + apqbo_NextUOR)

Similarly, to address the previous entry (when apqbo_PrevUOR not equal to 0):

rfy apqbo_UORentry based(addr(DSPAPQBO) + apqbo_PrevUOR)

Once addressability has been established to a UOR entry, addressability to the ith database for this UOR is given by:

rfy apqbo_DBent based(addr(apqbo_UORentry) + apqbo_DBoffset + (i-1) apqbo_DBLength)

Figure 13. Format of the output from QUERY TYPE=BACKOUT output request
**Database query request (TYPE=DB)**

You can use the Database Query request (DSPAPI FUNC=QUERY TYPE=DB) to retrieve information from the RECON concerning one or more registered databases.

This information includes the following database types:
- Full function
- Fast Path DEDB
- HALDB (returns information about the HALDB master and all of its partitions)
Optionally, you can request data set and area information. If you request this information, you can also request recovery-related information for the data set or area, including allocation, image copy, recovery, and reorganization information.

Syntax for the TYPE=DB query request
Parameters for the TYPE=DB query request

name  If used, begins in column 1.

TYPE=DB  Specifies that RECON information for one or more databases is requested.

TOKEN=address | (2 - 12)  Specifies the address of a 4-byte field that was returned on the
FUNCTION=STARTDBRC request.

DBNAME=symbol | symbol* | (2 - 12)  Specifies the name of the database whose information is being queried. This
name can be the name of a full-function database, a Fast Path DEDB, or a HALDB. You can
use the wildcard keyword * (an asterisk) at the end of a name to query databases whose names
match the pattern. In this case, the asterisk must be preceded by at least one alphabetic character.
You must specify a DBNAME or DBLIST if you do not specify LOC=FIRST.

DBLIST=namelist | (2 - 12)  Specifies the list of database names whose information is being queried. Each
name in the list can be the name of a Full Function database, a Fast Path DEDB, or a HALDB.

The list consists of a header and one or more eight-character list entries. The header consists
of a fullword containing the number of entries in the list. The name entries are left-aligned and are
padded with blanks.
You must specify a DBNAME or DBLIST if you do not specify LOC=FIRST.

DDN=ddname | (2 - 12) | NULL  Specifies the DD name of the data set or area. An asterisk (*) can be specified to return
information about all DBDSs or areas for the database. If a specific DD name is specified
with DBLIST or a DBNAME that specifies a HALDB, the specific DD name is ignored and treated as if
DDN=*$ was specified.

If you specify DDN=NULL, no DBDS or area information is returned. DDN=NULL is the default.

LIST=(ALLOC | IC | RECOV | REORG) | ALL | LIST=NULL  Specifies the type (or types) of supporting information to be included in the
query output for the specified DBDS or area.

If DDN is not specified, this information is returned for all DBDSs or areas in the database.
One or more of the specific values, separated by commas, can be included in the list: ALLOC (allocation records), IC (image copy records), RECOV (recovery records), or REORG (reorganization records). LIST=ALL specifies that all supporting information is requested.

To view information about HALDB online alter processing, specify LIST(REORG). The information about alter processing is included with the information about any other reorganization processes.

If you specify LIST=NONE, no supporting information is returned. LIST=NONE is the default.

LOC=FIRST | NEXT | SPEC
Specifies that the request is for either the specified, the first, or the next database defined in the RECON.

DBNAME=dbname is required when you specify LOC=NEXT or LOC=SPEC, but it is not allowed for LOC=FIRST.

Databases are in alphanumeric order. The next database might not necessarily be of the same type as the database name specified in the DBNAME parameter. The value in the DBNAME parameter is used as the base of the search and does not need to be a name of a database registered in the RECON.

LOC=SPEC is the default.

MF=S | L | M | E
Specifies the macro form of the request.

OUTPUT=output | (2 - 12)
Specifies a field to receive a pointer to the first block of a possible chain of database information blocks.

The output address is zero if no output was built. This can occur if nothing in the RECON satisfies the request or if an error occurs before any output could be built.

The storage for the output blocks is not pre-allocated by the caller. DBRC acquires storage from the specified subpool for these blocks. The caller must free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
Specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNCODE is specified, register 0 contains the reason code.
VERSION=2.0 | number
Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

Valid version numbers for the FUNC=QUERY TYPE=DB request are 1.0 and 2.0.

HALDB (master and all partitions) output

**Figure 16. Format of QUERY TYPE=DB (HALDB master and partitions) output**

The DBDS information is returned only if DDN is specified.
The following two examples describe the fields contained in the DSPAPQHB and DSPAPQHP blocks shown in Figure 16 on page 402. Refer to Figure 17 on page 406 for an illustration of the fields of the DBDS output.

Chapter 30. DBRC query request (QUERY)
Database not found output

This output block is returned when some of the databases specified in the DBLIST block could not be found in the RECON. One block is returned for each database that could not be found. The database name is included in the data area of this block.

When a database is not found, the macro call receives a return code of four (RC=4). If none of the databases in the list are found (RC=8), no output blocks are returned.

DSECT of DSPAPQNF

The following example describes the fields contained in the DSPAPQNF block shown in Figure 19.

Related concepts:
Chapter 26, “DBRC API,” on page 359

Related reference:
Chapter 30, “DBRC query request (QUERY),” on page 385
“DBDS query request (TYPE=DBDS)”
“HALDB partition query request (TYPE=PART)” on page 439

DBDS query request (TYPE=DBDS)

You can use the DSPAPI FUNC=QUERY TYPE=DBDS request to retrieve information from the RECON data set for one or more DBDSs in a non-HALDB
database, a HALDB partition, a DBDS group, or a CA group. You can also request recovery related information for the data set, including allocation, image copy, recovery, and reorganization information.

Syntax for the TYPE=DBDS query request

```plaintext
DSPAPI—FUNC=QUERY—TYPE=DBDS—TOKEN=address
```

Parameters for the TYPE=DBDS query request

**name**  
If used, begins in column 1.

**TYPE=DBDS**

Specifies that RECON information for a DBDS or area is requested.

Specifying DBDS with the TYPE parameter requires that you also specify a minimum version number of VERSION=2.0.

**TOKEN=address | (2 - 12)**

Specifies the address of a 4-byte field to receive the API token. This token must be included in all subsequent requests associated with this FUNC=STARTDBRC request.

**DBNAME=name | (2 -12)**

Specifies the database name (non-HALDB) or partition name of the DBDS being queried. This parameter is used when you are interested in a specific DBDS of a database or partition. Specifying a HALDB name is not allowed.

DBDNAME OR PARTNAME must be specified.
GROUP=name | (2 -12)
Specifies the name of a DBDS group or CA group containing the names of
the DBDSs being queried. The LOC or DDN parameters are not allowed
with this parameter.

DBNAME or GROUP must be specified. Database and recovery group
names are not allowed.

The wildcard GROUP=* can be used for all TYPE=xxxxGROUP queries,
but not for TYPE=DBDS. However, it can be used for TYPE=DBDSGROUP.

DDN=ddname | (2 -12)
Specifies the DD name of the data sets or areas. This parameter is used in
conjunction with the DBNAME parameter and the LOC parameter to
query a specific data set or the next or previous data set in the database or
partition. DDN=* returns information for all of the data sets or areas of the
database. DDN=* is the default when DBNAME is specified without
LOC=FIRST.

DDN must be specified with LOC=SPEC|NEXT.

When querying the next or previous data set, the value in the DDN
parameter is used as the base of the search and does not need to be a DD
name of a DBDS registered in RECON for the database or partition.

LIST=NONE | LIST=({ALLOC},{IC},{RECOV},{REORG}) | LIST=ALL
Specifies the types of supporting information to be included in the query
output for the returned DBDS. One or more of the specific values is
included in the list - ALLOC (allocation records), IC (image copy records),
RECOV (recovery records), or REORG (reorganization records). LIST=ALL
is specified if all supporting information is requested. LIST=NONE is
specified if no supporting information is requested.

LIST=NONE is the default.

LOC=FIRST | NEXT | SPEC
(Optional) - Specifies that the request is for the specified partition (SPEC),
the first, or the next DBDS defined in RECON for the database or partition.
DBNAME is required with the LOC parameter. DDN, with no wildcard, is
required with LOC=NEXT|SPEC. DDN is not allowed with LOC=FIRST.
LOC=SPEC is the default when a specific DDN is specified. LOC is not
allowed with GROUP.

Specify DDN=* to also request data set or area information. If you specify
a specific DDN (DDN=ddn), the specified DDN is ignored and all data set
or area information is returned.

Partitions are returned in high key order if the HALDB uses high keys.
Otherwise, partitions are returned in alphanumerical order.

RETCODE=returncode | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive
the return code. If specified as a register, the register must contain the
address of a word of storage to receive the return code. Regardless of
whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage
to receive the reason code. If specified as a register, the register must
contain the address of a word of storage to receive the reason code.
Regardless of whether RSNCODE is specified, register 0 contains the
reason code.
OUTPUT=output | (2 - 12)
  Specifies a field to receive a pointer to the first of a possible chain of blocks
  that contain the information for the partition.

  The output address is zero if no output was built. This result can occur if
  nothing in the RECON satisfies the request or if an error occurs before any
  output could be built.

  The storage for the output blocks is not preallocated by the caller. DBRC
  acquires storage from the specified subpool for these blocks. The caller
  must free this storage using the Buffer Release service (DSPAPI
  FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
  Optional parameter that specifies the subpool number for the storage being
  obtained. If not specified, the default is the subpool specified by the
  FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

MF=S | L | M | E
  Specifies the macro form of the request.

VERSION=2.0 | number
  Optional parameter that specifies the version number of the parameter list
  to be generated by this macro.

  To use the parameters associated with a version, you must specify the
  number of that version or a later version. If you specify an earlier version
  level, the parameter is not accepted by macro processing, and an error
  message is issued at assembly time. If parameters have a version
  dependency, the parameter descriptions with each request type identify the
  version number required.

  The default version is 2.0.

  Note: TYPE=DBDS requires that you specify a minimum version number
  of API VERSION=2.0.

Parameter error

- X'00000030' X'C9000001' The function (FUNC) specified in the parameter list that is passed to the API is invalid.
- X'00000030' X'C9000002' Invalid TOKEN field address. The address of the field containing the API TOKEN failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'C9000003' Invalid RETCODE field address. The address of the field to contain the API RETCODE failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'C9000004' Invalid RSNCODE field address. The address of the field to contain the API RSNCODE failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'C9000005' Invalid OUTPUT field address. The address of the field to contain the OUTPUT address failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'C9000008' Invalid DBNAME or GROUP address. The address of the field containing the DBNAME or GROUP failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'C9000009' Invalid DDN address. The address of the field containing the DDN failed validity checking. The address specifies storage that is not owned by the calling program.
- X'00000030' X'D8000001' Missing or invalid OUTPUT parameter.
- X'00000030' X'D8000002' Invalid value specified for TYPE parameter.
- X'00000030' X'D8000003' Query TYPE=DBDS requires a minimum API version of 2.0.
- X'00000030' X''D8210001' The DBNAME or GROUP is required.
- X'00000030' X'D8210002' DDN specified with invalid LOC value. Only LOC=NEXT|SPEC can be entered.
- X'00000030' X'D8210003' Invalid LOC value. When no DDN is specified only LOC=FIRST can be used.
- X'00000030' X'D8210004' The DDN parameter is not allowed with GROUP parameter.
- X'00000030' X'D8210005' The LOC is not allowed with GROUP parameter.
The following block mappings relate to the TYPE=DB and TYPE=DBDS request:

- DSPAPQAR – Fast Path AREA block
- DSPAPQDS – DBDS block
- DSPAPQEL – EEQE List
- DSPAPQSL – Subsystem List (Fast Path only)
- DSPAPQRI – Recovery Information (RCVINFO) block
- DSPAPQAL – Allocation block
- DSPAPQIC – Image Copy block
- DSPAPQRV – Recovery block
- DSPAPQRRR – Reorganization block

Group query request (TYPE=*GROUP)

You can use the Group query (DSPAPI FUNC=QUERY TYPE=*GROUP) request to retrieve group and member information for various types of groups that are registered in the RECON data set.

The following list outlines the groups that you can retrieve information for through the Group query (DSPAPI FUNC=QUERY TYPE=*GROUP) request:

- DBDS group (TYPE=DBDSGROUP)
- DB group (TYPE=DBGROUP)
- Recovery group (TYPE=RECOVGROUP)
- CA group (TYPE=CAGROUP)
- Global service group (TYPE=GSGROUP)

Subsections:
- “Syntax for the TYPE=*GROUP query request”
- “Parameters for the TYPE=*GROUP query request” on page 419
- “Return and reason codes for the TYPE=*GROUP query request” on page 420
- “Output for the TYPE=*GROUP query request” on page 422
- “Output for QUERY TYPE=DBDSGROUP, DBGROUP, and RECOVGROUP” on page 422
- “DSECT of DSPAPQDG” on page 422
- “Output for QUERY TYPE=CAGROUP” on page 423
- “DSECT of DSPAPQCG” on page 424
- “DSECT of DSPAPQCA” on page 424
- “Output for QUERY TYPE=GSGROUP” on page 425
- “DSECT of DSPAPQGG” on page 425

Syntax for the TYPE=*GROUP query request
Parameters for the TYPE=*GROUP query request

**name**  Optional symbol you can specify. If used, begins in column 1.

**TYPE=** DBDSGROUP | DBGROUP | RECOVGROUP | CAGROUP | GSGROUP

Specifies the type of group for which information is requested.

**CAINFO=** YES | NO

Specifies whether CA execution information is to be included with the CAGROUP information. CAINFO is valid only with TYPE=CAGROUP. CAINFO defaults to NO when TYPE=CAGROUP is specified, indicating that only the CA group member information is requested.

If CAINFO=NO is specified or if CAINFO=YES is specified and no CA execution information exists, the block-dependent pointer (apqhd_depptr) in the header of the CAGROUP block is 0.

**TOKEN=** symbol | (2 - 12)

Specifies the address of a 4-byte field that was returned on the FUNC=STARTDBRC request.

**GROUP=** * | symbol | symbol* | (2 - 12)

Specifies the name of the group being queried. You can use the wildcard keyword * (an asterisk) alone to request information about all groups. You can also use the wildcard at the end of a name, in which case the asterisk must be preceded by at least one alphabetic character. The default is GROUP=*

Either the GROUP keyword or the NAME keyword can be used. GROUP is preferred. NAME is accepted for compatibility.
NAME= * | symbol | symbol* | (2 - 12)
See the GROUP parameter.

MF=S | L | M | E
Specifies the macro form of the request.

OUTPUT=output | (2 - 12)
Specifies a field to receive a pointer to the first block of a possible chain of
group information blocks. See “Output for the TYPE=GROUP query
request” on page 422 for a detailed description of the information blocks
returned.

The output address is zero if no output was built which can occur if
nothing in the RECON satisfies the request or if an error occurs before any
output could be built.

The storage for the output blocks is not preallocated by the caller. DBRC
acquires storage from the specified subpool for these blocks. The caller
must free this storage using the Buffer Release service (DSPAPI
FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
Specifies the subpool number for the storage being obtained. If not
specified, the default is the subpool specified by the FUNC=STARTDBRC
request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive
the return code. If specified as a register, the register must contain the
address of a word of storage to receive the return code. Regardless of
whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage
to receive the reason code. If specified as a register, the register must
contain the address of a word of storage to receive the reason code.
Regardless of whether RSNCODE is specified, register 0 contains the
reason code.

VERSION=2.0 | number
Specifies the version number of the parameter list to be generated by this
request.

To use the parameters associated with a version, you must specify the
number of that version or a later version. If you specify an earlier version
level, the parameter is not accepted by macro processing, and an error
message is issued at assembly time. If parameters have a version
dependency, the parameter descriptions with each request type identify the
version number required.

Valid version numbers for the FUNC=QUERY TYPE=xxxxGROUP request
are 1.0 and 2.0.

Return and reason codes for the TYPE=GROUP query request

Chapter 30. DBRC query request (QUERY) 425
Log query request (TYPE=LOG)

You can use the Log query (DSPAPI FUNC=QUERY TYPE=LOG) request to retrieve log information from RECON for a specific instance of a subsystem.

If the request is for non-RSR logs or RSR active subsystem logs, information from the following RECON data sets is returned:

- PRILOG
- LOGALL
- SECLOG (if applicable)
- PRISLDS (if applicable)
- SECSLDS (if applicable)

If the request is for RSR tracking subsystem logs, information from the following RECON data sets is returned:

- PRITSLDS
- SECTSLDS (if applicable)

The log query request can also return log information for subsystems that started in a specified time range. This request can also be used for a specific subsystem.

Subsections:

- "Syntax for the TYPE=LOG query request" on page 427
- "Parameters for the TYPE=LOG query request" on page 427
- "Return and reason codes for the TYPE=LOG query request" on page 429
Syntax for the TYPE=LOG query request

```
name DSPAPI—FUNC=QUERY—TYPE=LOG—TOKEN=address

STARTIME=time LOC=SPEC
FROMTIME=time TOTIME=time

TRACKER=NO TRACKER=YES SSID=subsystem_ID

RSNCODE=reasoncode OUTPUT=output

SUBPOOL=0 SUBPOOL=number

VERSION=2.0
```

Parameters for the TYPE=LOG query request

**name**  Optional symbol you can specify. If used, begins in column 1.

**TYPE=LOG**  
Specifies that log information is requested.

**TOKEN=address | (2 - 12)**  
Specifies the address of a 4-byte field that was returned on the FUNC=STARTDBRC request.

**STARTIME=time | (2-12)**  
Specifies the time stamp field that contains the start time of the requested log. The time is a packed decimal time stamp in UTC format.
FROMTIME=\texttt{time} \ (2-12)
Specifies the time stamp field that limits the logs requested to those whose subsystem started at, or after, the specified time. The time is a packed decimal time stamp in UTC format.
If you specify this parameter, you must also specify a minimum version number of DBRC API VERSION=2.0.

TOTIME=\texttt{time} \ (2-12)
Specifies the time stamp field that limits the logs requested to those whose subsystem started at, or before, the specified time. The time is a packed decimal time stamp in UTC format. This parameter may be used along with the FROMTIME parameter.
If you specify this parameter requires that you also specify a minimum version number of API VERSION=2.0.

SSID=\texttt{subsystem\_ID} \ (2-12)
Specifies the subsystem name for the log being queried. SSID is required for RSR tracking subsystem log queries (TRACKER=YES). Otherwise you can specify the SSID parameter only when requesting the previous or next log of a specific subsystem, for example, when LOC previous or next is specified, or a range of logs for a specific subsystem using the FROMTIME or TOTIME parameters.

LOC=\texttt{PREV} | \texttt{NEXT} | \texttt{SPEC}
Specifies that the request is for the log with a specified start time (LOC=SPEC), a start time preceding the specified start time (LOC=PREV), or a start time following the specified start time (LOC=NEXT). The STARTTIME parameter is used as the base of the search and does not need to be the start time of a login RECON.
LOC=SPEC is the default.

TRACKER=\texttt{NO} | \texttt{YES}
Specifies whether log information is being requested for an RSR tracking subsystem or not. Specify TRACKER=YES to request the RSR tracker's log information. Specify TRACKER=NO to request log information from a non-RSR subsystem or an active subsystem of an RSR system. TRACKER=NO is the default.

MF=\texttt{S} | \texttt{L} | \texttt{M} | \texttt{E}
Specifies the macro form of the request.

OUTPUT=\texttt{output} \ (2 - 12)
Specifies a field to receive a pointer to the first block of a possible chain of log information blocks.
The output address is zero if no output was built. This can occur if nothing in the RECON satisfies the request or if an error occurs before any output could be built.
The storage for the output blocks is not pre-allocated by the caller. DBRC acquires storage from the specified subpool for these blocks. The caller must free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) and specify the returned output address.

SUBPOOL= \texttt{0} \ (\texttt{number})
Specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.
RETCODE=$returncode$ | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.

RSNCODE=$reasoncode$ | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNCODE is specified, register 0 contains the reason code.

VERSION=2.0 | $number$
Specifies the version number of the parameter list that is generated by this macro.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

Valid version numbers for the FUNC=QUERY TYPE=LOG request are 1.0 and 2.0.

OLDS query request (TYPE=OLDS)

You can use the OLDS query (DSPAPI FUNC=QUERY TYPE=OLDS) request to retrieve online log data set information from the RECON for a specific subsystem or all subsystems.

Syntax for the TYPE=OLDS query request

```plaintext
DSPAPI—FUNC=QUERY—TYPE=OLDS—TOKEN=address

SSID=*
SSID=subsystem_ID

MF=S
MF=(S,list)
MF=(L,list)
MF=(M,list)
MF=(E,list)

OUTPUT=output

SUBPOOL=0
SUBPOOL=number

RETCODE=returncode
RSNCODE=reasoncode

VERSION=2.0
VERSION=number
```

Parameters for the TYPE=OLDS query request

- **name**: Optional symbol you can specify. If used, begins in column 1.
TYPE=OLDS
   Specifies that online log data set information is requested.

TOKEN=symbol | (2 - 12)
   Specifies the address of a 4-byte field that was returned on the
   FUNC=STARTDBRC request.

SSID=* | symbol* | symbol | (2 - 12)
   Specifies the subsystem name for the backout being queried. You can use
   the wildcard keyword * (an asterisk) alone to request all of the OLDS
   information (SSID=*, the default). You can also use it at the end of a name
   to query subsystem names that match the pattern. In this case, the asterisk
   must be preceded by at least one alphabetic character.

MF=S | L | M | E
   Specifies the macro form of the request.

OUTPUT=output | (2 - 12)
   Specifies a field to receive a pointer to the first block of a possible chain of
   OLDS information blocks.

   The output address is zero if no output was built. This can occur if nothing
   in the RECON satisfies the request or if an error occurs before any output
   could be built.

   The storage for the output blocks is not pre-allocated by the caller. DBRC
   acquires storage from the specified subpool for these blocks. The caller
   must free this storage using the Buffer Release service (DSPAPI
   FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
   Specifies the subpool number for the storage being obtained. If not
   specified, the default is the subpool specified by the FUNC=STARTDBRC
   request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2-12)
   If specified as a symbol, specifies the label of a word of storage to receive
   the return code. If specified as a register, the register must contain the
   address of a word of storage to receive the return code. Regardless of
   whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
   If specified as a symbol, the symbol must be the label of a word of storage
   to receive the reason code. If specified as a register, the register must
   contain the address of a word of storage to receive the reason code.
   Regardless of whether RSNCODE is specified, register 0 contains the
   reason code.

VERSION=2.0 | number
   Specifies the version number of the parameter list to be generated by this
   request.

   To use the parameters associated with a version, you must specify the
   number of that version or a later version. If you specify an earlier version
   level, the parameter is not accepted by macro processing, and an error
   message is issued at assembly time. If parameters have a version
   dependency, the parameter descriptions with each request type identify the
   version number required.

   Valid version numbers for the FUNC=QUERY TYPE=OLDS request are 1.0
   and 2.0 (default).

HALDB partition query request (TYPE=PART)

You can use the DSPAPI FUNC=QUERY TYPE=PART request to retrieve information for a particular HALDB partition from the RECON data set. You can request data set information for a specific DBDS or all DBDSs in the partition, and can optionally request recovery-related information for the data set, including allocation, image copy, recovery, and reorganization information.

Syntax for the TYPE=PART query request

```plaintext
DSPAPI—FUNC=QUERY—TYPE=PART—TOKEN=address
```
Parameters for the TYPE=PART query request

name  Optional symbol you can specify. If used, begins in column 1.

TYPE=PART
   Required parameter that specifies that RECON data set information for a
   HALDB partition is requested.

   When you specify the TYPE=PART, you must also specify a minimum
   DBRC API version number of VERSION=2.0.

DBNAME=name  | (2 - 12)
   Specifies the HALDB name of the partition being queried. You can
   optionally specify the LOC parameter, which indicates that you are
   interested in either the first partition, last partition, or all partitions of the
   specified HALDB. If the HALDB uses high keys, the request is for the
   partition with the lowest or highest high key. Otherwise, the first or last
   alphanumerical partition is returned. LOC=SPEC|PREV|NEXT may not be
   specified.

PARTNAME=name  | (2 - 12)
   Required parameter that specifies the name of a HALDB partition being
   queried.

   The LOC parameter indicates the partition of interest:
   • The default LOC=SPEC indicates a request for the specified partition.
     This partition might be available or disabled.
   • LOC=PREV indicates a request for the active partition in the HALDB
     that is before the specified partition. If the HALDB uses high keys, the
     request is for the partition with the lower high key. Otherwise, the
     previous alphanumerical partition within the HALDB is returned. The
     partition name specified must be the name of an active partition
     registered in the RECON. This is required in order to ensure that the
     previous partition is within the same HALDB
• LOC=NEXT indicates a request for the active partition in the HALDB that is after the specified partition. If the HALDB uses high keys, the request is for the partition with the higher high key. Otherwise, the next alphanumerical partition within the HALDB is returned. The partition name specified must be the name of an active partition registered in the RECON. This is required to ensure that the next partition is within the same HALDB.

• LOC=FIRST | LAST can not be specified with PARTNAME.

To use this parameter, you must also specify a minimum version number of API VERSION=2.0.

DDN=NULL \text{| (2 - 12) | * | ddname}

Specifies the DD name of a DBDS set within the partition. An asterisk (* without quotes) can also be specified indicating that information about all DBDSs is requested. If a specific DDN is requested and the request is not for a specific partition information is returned for all DBDSs of the partition.

DDN=NULL indicates that no DBDS information is requested. This is the default.

LIST=( {ALLOC},{IC},{RECOV},{REORG}) \text{| LIST=ALL | LIST=NONE}

Specifies the types of supporting information to be included in the query output for the specified DBDS. If DDN is not specified, this information is returned for all DBDSs in the partition. One or more of the specific values is included in the list: ALLOC (allocation records), IC (image copy records), RECOV (recovery records), or REORG (reorganization records). LIST=ALL requests all supporting information. LIST=NONE requests no supporting information.

LOC=ALL | FIRST | LAST | PREV | NEXT | SPEC

The optional parameter specifies that the request is for the specified partition (SPEC), or for the first, last, previous, next or all active partitions defined in RECON for the HALDB. LOC=SPEC may return an active or disabled partition. DBNAME is required with LOC=FIRST | LAST | ALL, but is not allowed with LOC=PREV | NEXT | SPEC. Conversely, PARTNAME is required with LOC=PREV | NEXT | SPEC, but is not allowed with LOC=FIRST | LAST | ALL. LOC=ALL is the default with DBNAME. LOC=SPEC is the default with PARTNAME.

Partitions are returned in high key order if the HALDB uses high keys. Otherwise, partitions are returned in alphanumerical order.

TOKEN=\text{address} \text{| (2 - 12)}

Specifies the address of a 4-byte field to receive the API token. This token must be included in all subsequent requests associated with this FUNC=STARTDBRC request.

RETCODE=\text{returncode} \text{| (2 - 12)}

Specifies a location in storage to receive the return code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the return code is placed in register 15.

RSNCODE=\text{reasoncode} \text{| (2 - 12)}

Specifies a place in storage to receive the reason code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the reason code is placed in register 0.
OUTPUT=\texttt{output} | (2 - 12)

Required parameter that specifies a field to receive a pointer to the first of a possible chain of blocks that contain the information for the partition.

The output address is 0 if no output is built. This can happen if nothing in the RECON data set satisfies the request or if an error occurs before any output is built.

The storage for the output blocks is not pre-allocated by the caller. DBRC acquires storage from the specified subpool for these blocks. The caller must free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) and specify the returned output address.

\textbf{SUBPOOL= 0 | \textit{number}}

Optional parameter that specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

\textbf{MF=S | L | M | E}

Specifies the macro form of the request.

\textbf{VERSION=2.0 | \textit{number}}

Optional parameter that specifies the version number of the parameter list that is generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted for processing and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

The default version is 2.0.

\textbf{Note: TYPE=PART requires that you specify a minimum version number of API VERSION=2.0.}

Return and reason codes for the TYPE=PART query request

The following table contains most of the return and reason codes for TYPE=PART query requests. The other possible return and reason codes relate to DBRC, not the query request.

RECON status query request (TYPE=RECON)

You can use the RECON status query (DSPAPI FUNC=QUERY TYPE=RECON) request to retrieve information pertaining to the RECON data sets, including RECON header information as well as the status of each RECON data set.

Syntax for the TYPE=RECON query request

```c
name DSPAPI — FUNC=QUERY — TYPE=RECON — TOKEN=address
```
Parameters for the TYPE=RECON query request

name  Optional symbol you can specify. If used, begins in column 1.

TYPE=RECON
  Specifies that RECON status information is requested.

TOKEN=symbol | (2 - 12)
  Required parameter that specifies the address of a 4-byte field that was
  returned on the FUNC=STARTDBRC request.

MF=S | L | M | E
  Optional parameter that specifies the macro form of the request.

OUTPUT=output | (2 - 12)
  Specifies a field to receive a pointer to the RECON status information
  block.
  The output address is zero if no output was built. This can occur if nothing
  in the RECON satisfies the request or if an error occurs before any output
  could be built.
  The storage for the output blocks is not preallocated by the caller. DBRC
  acquires storage from the specified subpool for these blocks. The caller
  must free this storage using the Buffer Release service (DSPAPI
  FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
  Optional parameter that specifies the subpool number for the storage being
  obtained. If not specified, the default is the subpool specified by the
  FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2-12)
  If specified as a symbol, specifies the label of a word of storage to receive
  the return code. If specified as a register, the register must contain the
  address of a word of storage to receive the return code. Regardless of
  whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
  If specified as a symbol, the symbol must be the label of a word of storage
  to receive the reason code. If specified as a register, the register must
  contain the address of a word of storage to receive the reason code.
  Regardless of whether RSNCODE is specified, register 0 contains the
  reason code.
VERSION=2.0 | number

Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

Valid version numbers are 1.0 and 2.0.

Subsystem query request (TYPE=SUBSYS)

You can use the Subsystem query (DSPAPI FUNC=QUERY TYPE=SUBSYS) request to retrieve subsystem information from the RECON data set for a specific subsystem or all subsystems.

Syntax for the TYPE=SUBSYS query request
Parameters for the TYPE=SUBSYS query request

name  Optional symbol you can specify. If used, begins in column 1.

TYPE=SUBSYS
   Specifies that subsystem information is requested.

TOKEN=address  | (2 - 12)
   Specifies the address of a 4-byte field that was returned on the
   FUNC=STARTDBRC request.
SSID= * | name* | name | (2 - 12)
Specifies the name of the subsystem being queried. You can use the wildcard keyword * (an asterisk) alone to request information about all subsystems (SSID=*, the default). You can also use it at the end of a name to query subsystems whose names match the pattern. In this case, the asterisk must be preceded by at least one alphabetic character.

SSYTYPE=ALL | ONLINE | BATCH | DBRCAPI
Specifies the type of subsystem for which information is being requested. You cannot specify this parameter if you also specify a specific subsystem name for the SSID parameter or if you specify TRACKER=YES. SSTYPE=DBRCAPI requires that you specify a minimum version number of VERSION=2.0. SSTYPE=ALL is the default.

TRACKER=YES | NO
Specifies whether log information is being requested for an RSR tracking subsystem. Specify TRACKER=YES to request the RSR tracker log information. Specify TRACKER=NO to request log information from a non-RSR subsystem or an active subsystem of an RSR system. TRACKER=NO is the default.

MF=S | L | M | E
Optional parameter that specifies the macro form of the request.

OUTPUT=output | (2 - 12)
Specifies a field to receive a pointer to the first block of a possible chain of subsystem information blocks.

The output address is 0 if no output was built which can occur if nothing in the RECON satisfies the request or if an error occurs before any output is built.

The storage for the output blocks is not preallocated by the caller. DBRC acquires storage from the specified subpool for these blocks. The caller must free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) and specify the returned output address.

SUBPOOL= 0 | number
Specifies the subpool number for the storage being obtained. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2 - 12)
Specifies a place in storage to receive the return code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the return code is placed in register 15.

RSNCODE=reasoncode | (2 - 12)
Specifies a place in storage to receive the reason code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the reason code is placed in register 0.

VERSION=2.0 | number
Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error
message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

Valid version numbers for the FUNC=QUERY TYPE=SUBSYS request are 1.0 and 2.0.

Related reference:
- Chapter 30, “DBRC query request (QUERY),” on page 385
Chapter 31. DBRC release buffer request (RELBUF)

You can use the DBRC release buffer request (DSPAPI FUNC=RELBUF) to release storage that was acquired as a result of DBRC query, command, authorization, and unauthorization requests.

Each request returns a chain of one or more blocks containing the requested information. It is the caller’s responsibility to ensure that the storage DBRC allocated for these blocks is freed.

Syntax for the RELBUF request

```
name
DSPAPI—FUNC=RELBUF—TOKEN=address—BUFFER=buffer

MF=S
MF=(S,list)  RETCODE=returncode
MF=(L,list)
MF=(M,list)
MF=(E,list)

NOCHECK
COMPLETE

version
RSNCODE=reasoncode
VERSION=2.0

```

Parameters for the RELBUF request

**name**  Optional symbol you can specify. If used, begins in column 1.

**TOKEN=address**  | (2 - 12)
Required parameter that specifies the address of a 4-byte field that was returned on the FUNC=STARTDBRC request.

**BUFFER=buffer**  | (2 - 12)
Specifies a field containing the address of the first block of a chain of one or more information blocks to release. This storage was acquired by DBRC in order to satisfy another DBRC request.

**RETCODE=returncode**  | (2 - 12)
Specifies a place in storage to receive the return code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the return code is placed in register 15.

**RSNCODE=reasoncode**  | (2 - 12)
Specifies a place in storage to receive the reason code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the reason code is placed in register 0.
MF=S | L | M | E

Specifies the macro form of the request.

**VERSION=2.0 | number**

Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted for processing and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

**Related concepts:**
Chapter 32. DBRC start request (STARTDBRC)

You can use the DBRC start request (STARTDBRC) to initialize the DBRC API and to start DBRC.

Syntax for the STARTDBRC request

Syntax:

```
name DSPAPI FUNC=STARTDBRC TOKEN=address SYSPRINT=ddname
```

```
READONLY=NO SSID=NULL GSGNAME=NULL RECON1=ddname
```

```
READONLY=YES SSID=NULL GSGNAME=NULL RECON1=ddname RECON2=ddname RECON3=ddname IMS=ddname SUBPOOL=0 SUBPOOL=number
```

```
MF=S MF=(S,list) RETCODE=returncode
```

```
MF=(L,list) MF=(M,list),COMPLETE MF=(E,list),COMPLETE
```

```
MF=(M,list),NOCHECK
```

```
RSNCODE=reasoncode VERSION=2.0
```

Parameters for STARTDBRC

- **name**: Optional symbol you can specify. If used, begins in column 1.

- **TOKEN=address | (2 - 12)**
  Specifies the address of a 4-byte field to receive the API token. This token must be included in all subsequent requests associated with this STARTDBRC request.

- **SYSPRINT= ddname | (2 - 12)**
  Specifies the address of an 8-byte field that contains the DD name of an output data set to be used for messages. If omitted, the default name SYSPRINT is used.

- **READONLY=NO | YES**
  Specifies whether (YES) or not (NO) the application needs read only access to the DBRC information. READONLY=NO requires that the application has a minimum of UPDATE level authority to the RECON data sets.
To use this parameter, you must specify API VERSION=2.0 or later.

**SSID=NULL | name**

Specifies the address of an 8-byte field that contains the subsystem name that is used to register with DBRC. If you specify SSID=NULL, registration with DBRC is not done. Do not specify both READONLY=YES and SSID=symbol.

The default is SSID=NULL. To use this parameter, you must specify API VERSION=2.0 or later.

**GSGNAME=name | (2 - 12)**

Specifies the address of an 8-byte field that contains the name of a global service group (GSG). The GSG name must be known to DBRC. The default name is NULL, which specifies no GSG.

To use this parameter, you must also specify API VERSION=2.0 or later.

**RECON1=ddname | (2 - 12)**

Specifies the address of an 8-byte field that contains the DD name that is used in place of the default DD name RECON1.

If omitted, the default name RECON1 is used. To use this parameter, you must specify API VERSION=2.0 or later.

**RECON2=ddname | (2 - 12)**

Specifies the address of an 8-byte field that contains the DD name that is used in place of the default DD name RECON2.

If omitted, the default name RECON2 is used. To use this parameter, you must specify API VERSION=2.0 or later.

**RECON3=ddname | (2 - 12)**

Specifies the address of an 8-byte field that contains the DD name that is used in place of the default DD name RECON3.

If omitted, the default name RECON3 is used. To use this parameter, you must specify API VERSION=2.0 or later.

**IMS=IMS | ddname**

Specifies the address of an 8-byte field that contains the DD name that is used in place of the default DD name IMS.

The default is IMS=IMS. To use this parameter, you must also specify API VERSION=2.0 or later.

**SUBPOOL=0 | number**

Specifies the default subpool number that is to be used for all requests (for example QUERY and AUTH) that return storage. For information on valid subpools for your program, see the z/OS MVS Assembler Services Guide.

SUBPOOL=0 is the default for the request if SUBPOOL is not specified here or on the request.

**MF=S | L | M | E**

Specifies the macro form of the request.

**RETCODE=returncode | (2 - 12)**

Specifies a place in storage to receive the return code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the return code is placed in register 15.
RSNCODE=reasoncode | (2 - 12)
Specifies a place in storage to receive the reason code. If specified as a symbol, the symbol must be the label of a word of storage. If specified as a register, the register must contain the address of a word of storage. If not specified, the reason code is placed in register 0.

VERSION=2.0 | number
Specifies the version number of the parameter list that is generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted for processing and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the required version number.

Related concepts:

- Chapter 26, “DBRC API,” on page 359
- “Macro forms of the DSPAPI macro” on page 362
You can use the STOPDBRC request to terminate the DBRC application and to stop DBRC.

If the application registered to DBRC by supplying an SSID on the STARTDBRC request, a subsystem record for the application was recorded in RECON. The STOPDBRC request automatically deregisters the application, unauthorizing any authorized databases and deleting the subsystem record.

**Syntax for the STOPDBRC request**

```
DSPAPI—FUNC=STOPDBRC—TOKEN=address
```

- **MF=S**
- **MF=(S,list)**
- **MF=(L,list)**, COMPLETE
- **MF=(M,list)**, NOCHECK, COMPLETE
- **MF=(E,list)**, NOCHECK

```
RETCODE=returncode
RSNCODE=reasoncode
VERSION=1.0
VERSION=number
```

**Parameters for STOPDBRC**

- **name**  Optional symbol you can specify. If used, begins in column 1.
- **TOKEN=symbol | (2 - 12)**
  Specifies the address of a 4-byte field that was returned on the FUNC=STARTDBRC request.
- **RETCODE=returncode | (2-12)**
  If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.
- **RSNCODE=reasoncode | (2-12)**
  If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNCODE is specified, register 0 contains the reason code.
- **MF=S | L | M | E**
  Specifies the macro form of the request.
VERSION=1.0 | number
Specifies the version number of the parameter list to be generated by this request.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted for processing and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

Return and reason codes for STOPDBRC

Related concepts:
Chapter 26, “DBRC API,” on page 359
“Macro forms of the DSPAPI macro” on page 362
Chapter 34. DBRC unauthorization request (UNAUTH)

You can use the UNAUTH request to explicitly remove authorization to a database or area. Authorization by an application is implicitly removed by the STOPDBRC request. UNAUTH is the opposite of FUNC=AUTH.

Syntax for the UNAUTH request

```
name
DSPAPI FUNC=UNAUTH TOKEN=address AUTHLIST=name OUTPUT=output
```

Parameters for the UNAUTH request

**name**

Optional parameter. Begin name in column 1.

**TOKEN=address | (2-12)**

Specifies the address of the API token which was returned on the FUNC=STARTDBRC macro.

**AUTHLIST=name | (2 - 12)**

Specifies the list of database names or Fast Path areas to be unauthorized. The list consists of a fullword containing the number of elements in the list, a fullword containing the length of an element, followed by one or more elements. Each element consists of an 8 character DB name or Fast Path DEDB name and 8 characters of blanks (X'40') or a Fast Path area name.

**OUTPUT=output | (2-12)**

Specifies a field to receive a pointer to the authorization output block DSPAPAUB.

The output address is zero if no output was built. This can happen if an error occurs before any output could be built.

The storage for the output blocks is not pre-allocated by the caller. DBRC acquires storage from the specified subpool for these blocks. It is the responsibility of the caller to free this storage using the Buffer Release service (DSPAPI FUNC=RELBUF) specifying the returned output address.
SUBPOOL= 0 | number
Specifies the subpool number for the storage being obtained. See the z/OS MVS Programming: Assembler Services Guide for information on valid subpools for your program. If not specified, the default is the subpool specified by the FUNC=STARTDBRC request. Otherwise, subpool 0 is the default.

RETCODE=returncode | (2-12)
If specified as a symbol, specifies the label of a word of storage to receive the return code. If specified as a register, the register must contain the address of a word of storage to receive the return code. Regardless of whether RETCODE is specified, register 15 contains the return code.

RSNCODE=reasoncode | (2-12)
If specified as a symbol, the symbol must be the label of a word of storage to receive the reason code. If specified as a register, the register must contain the address of a word of storage to receive the reason code. Regardless of whether RSNODE is specified, register 0 contains the reason code.

VERSION=2.0 | number
Specifies the version number of the parameter list to be generated by this macro.

To use the parameters associated with a version, you must specify the number of that version or a later version. If you specify an earlier version level, the parameter is not accepted by macro processing, and an error message is issued at assembly time. If parameters have a version dependency, the parameter descriptions with each request type identify the version number required.

The valid version number for the FUNC=UNAUTH request is 2.0 (the default).

MF=S | L | M | E
Specifies the macro form of the request.

UNAUTH output block mapping

This figure illustrates the format of the output from a TYPE=UNAUTH request. The output block for the TYPE=UNAUTH request begins with a standard header that is mapped by the DSPAPQHD. The data portion of this output block is mapped by DSPAPAUB.

![Diagram of UNAUTH output block](image)

**UNAUTH output block**

This figure illustrates the output block that is returned by the UNAUTH request. The output block contains an array of authorized databases and indicates if the UNAUTH request was successful.

**Example of output block mapped by the DSPAPAUB**

472 System Programming APIs
Part 6. Repository Server batch interface (FRP BATCH)

The Repository Server (RS) address space batch interface (FRP BATCH) is a batch interface to manage the RS and the repositories.
Chapter 35. Commands for FRP BATCH

The Repository Server (RS) address space batch interface (FRP BATCH) is invoked from JCL as an executable job step program, and accepts commands through the SYSIN input stream.

Some MODIFY (F) and FRP BATCH commands are equivalent.

<table>
<thead>
<tr>
<th>MODIFY (F)</th>
<th>FRP BATCH</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>--</td>
<td>ADD</td>
<td></td>
</tr>
<tr>
<td>ADMIN DISPLAY</td>
<td>LIST</td>
<td></td>
</tr>
<tr>
<td>ADMIN START</td>
<td>START</td>
<td></td>
</tr>
<tr>
<td>ADMIN STOP</td>
<td>STOP</td>
<td>Stops the IMSRSC repository</td>
</tr>
<tr>
<td>--</td>
<td>RENAME</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>DELETE</td>
<td></td>
</tr>
<tr>
<td>ADMIN DSCHANGE</td>
<td>DSCHANGE</td>
<td></td>
</tr>
<tr>
<td>--</td>
<td>UPDATE</td>
<td></td>
</tr>
<tr>
<td>AUDIT</td>
<td>--</td>
<td>Changes the audit level</td>
</tr>
<tr>
<td>SECURITY</td>
<td>--</td>
<td>Refreshes in-storage profiles</td>
</tr>
<tr>
<td>SHUTDOWN</td>
<td>--</td>
<td>Stops the RS. Similar to the STOP command through the z/OS STOP (P) interface.</td>
</tr>
</tbody>
</table>

The job control statements are:

**EXEC**

Specifies the program name (PGM=FRP BATCH) and the program parameters. The parameters must be comma delimited and can be supplied in any order. Each parameter is in the format of parameter=value.

**XCFGROUP**

The name of the XCF group in which the RS is located. The value of this parameter is the same as the value of the XCF_GROUP_NAME parameter in the FRPCFG member of the IMS PROCLIB data set.

**LANG**

The language for output messages. Only ENU is supported. If this parameter is omitted, ENU is used.

The following example is an EXEC statement:

```
EXEC PGM=FRP BATCH, PARM=('XCFGROUP=FRPGRUP1', 'LANG=ENU')
```

**SYSPRINT DD**

Defines a data set for general messages and information. DCB attributes for this data set are RECFM=FBM and LRECL=133.

**FRPLIST DD**

Defines a data set for the LIST command output. If this statement is omitted, the output of the LIST command is written to the SYSPRINT DD output data set. DCB attributes for this data set are RECFM=FBM and LRECL=133.
The commands to be processed are specified on the SYSIN control cards. The SYSIN control cards must be entered in columns 1 - 72 of the input stream. Each statement has the following general form:

```
command_name parameter1 parameter2(value) /*inline comment
*Full-line comment
```

The following rules apply:

- The `command_name` is the first item of a command. It is followed by a space ( ), and one or more parameters.
- If a command contains more than one parameter, each parameter must be separated by one or more spaces ( ), a comma (,), or both.
- A parameter can have a value. The value of a parameter is enclosed in parentheses ( ).
- Command names, parameters, and values are converted by the program to uppercase.
- To enter an inline comment, type a forward slash followed by an asterisk (/ *). Subsequent characters on the same line are ignored by the program.
- To enter a full-line comment, type an asterisk (*) in column 1. All characters on that line are ignored by the program.
- To break a command over multiple lines, use one of the following continuation characters:
  - Use a hyphen (-) to separate parameters for the same command across multiple lines. The hyphen does not delete the leading separator from continued lines. For example:
    
    ```
    RENAME REPOSITORY(REPOSITORY_NAME) -
    REPOSITORYNEW(REPNEWNAME)
    ```
  - Use a plus sign (+) to enter a single parameter and its value on multiple lines. It deletes the leading separator from continued lines. The plus sign must immediately follow the last character on a line. For example:
    
    ```
    START REPOSITORY
    (REPOSITORY+ ORY_NAME)
    ```

The following sample is JCL that runs the FRPBATCH interface with the various FRPBATCH commands:

```c
//FRPBAT EXEC PGM=FRPBATCH,PARM='XCFGROUP=FRPGRUP1'
//SYSPRINT DD SYSOUT=
//SYSIN DD *
/*

ADD command for FRPBATCH

Use the ADD FRPBATCH command to add an IMSRSC repository to the Repository Server (RS) catalog repository data sets.

Subsections:
• “Syntax”
• “Keywords” on page 478

Syntax

ADD REPOSITORY(repository_name) REPDSN1RID(ds1_rid_dsname)
ADD REPDSN1RMD(ds1_rmd_dsname) REPDSN2RID(ds2_rid_dsname)
ADD REPDSN2RMD(ds2_rmd_dsname)
ADD REPDSN3RID(NULL) REPDSN3RMD(NULL) AUTOOPEN(YES)
ADD REPDSN3RID(ds3_rid_dsname) REPDSN3RMD(ds3_rmd_dsname) AUTOOPEN(NO)
ADD SECURITYCLASS(NULL)
ADD SECURITYCLASS(securityclassname)
Keywords

REPOSITORY()  
This is a required keyword. The name of the repository. The name can be up to 44 characters long. Valid characters are A-Z (uppercase only), 0-9, and the following symbols: number sign (#), dollar sign ($), at sign (@), period (.), and underscore (_). All lower case characters are converted to uppercase.

A repository name of CATALOG cannot be used, because it is reserved for RS usage.

REPDSN1RID()  
This is a required keyword. The primary repository index data set (RID). A valid existing VSAM key sequenced data set (KSDS) name is required for the repository to initialize.

REPDSN1RMD()  
This is a required keyword. The primary repository member data set (RMD). A valid existing VSAM KSDS name is required for the repository to initialize.

REPDSN2RID()  
This is a required keyword. The secondary RID. A valid existing VSAM KSDS name is required for the repository to initialize.

REPDSN2RMD()  
This is a required keyword. The secondary RMD. A valid existing VSAM KSDS name is required for the repository to initialize.

REPDSN3RID()  
This keyword is optional. The spare RID. If this parameter is not specified, the spare data set is set to NONE. If specified, it must be a valid VSAM KSDS data set name or NULL. Setting the REPDSN3 data set pair to NULL results in its status being set to NONE. The spare is not allocated until data set recovery processing is initiated.

REPDSN3RMD()  
This keyword is optional. The spare RMD. If this parameter is not specified, the spare data set is set to NONE. If specified, it must be a valid VSAM KSDS data set name or NULL. Setting the REPDSN3 data set pair to NULL results in its status being set to NONE. The spare is not allocated until data set recovery processing is initiated.

AUTOOPEN(YES | NO)  
This keyword is optional. Specifies when repository data sets are allocated.

YES  
Repository data sets are allocated when the repository is started. This is the default.

NO  
Repository data sets are allocated when you first connect to the repository.

SECURITYCLASS(NULL | securityclassname)  
This keyword is optional. Specifies the name of the security class to be used for the user repository. The name must be left-aligned, an 8-byte name with trailing contiguous spaces. The first character must be alphabetic and subsequent name characters alphanumeric.

If this parameter is omitted, or if NULL is specified, there is no security for this user repository. The name specified can be the same name as the value for SAF_CLASS specified for the RS address space in the FRPCFG member of the IMS PROCLIB data set.

Related concepts:
DELETE command for FRPBUCH

Use the DELETE FRPBUCH command to remove an IMSRSC repository from the Repository Server (RS) catalog repository data sets.

**Note:** When you remove a repository from the RS catalog repository, its data sets are not deleted. To delete the data sets, use the z/OS Access Method Services (IDCAMS) utility or a similar method after you have removed the repository from the RS catalog repository.

Subsections:
- “Syntax” on page 480
- “Keywords” on page 480

**Syntax**

```
DELETE REPOSITORY(repository_name)
```

**Keywords**

**REPOSITORY()**

This is a required keyword. The name of the repository to be removed. "CATALOG" is reserved for internal use and cannot be deleted.

Related concepts:
- Overview of the IMSRSC repository (System Definition)

Related tasks:
- Removing an IMSRSC repository from the RS catalog repository (System Administration)

Related reference:

DSCHANGE command for FRPBUCH

Use the DSCHANGE FRPBUCH command to change the status of an IMSRSC repository data set pair to either DISCARD or SPARE.

Subsections:
- “Syntax” on page 480
- “Keywords” on page 480
Syntax

```
DSCHANGE REPOSITORY(repository_name) RDS(1 | 2 | 3) ACTION(SPARE | DISCARD)
```

Keywords

**REPOSITORY()**
This is a required keyword. The name of the repository to be changed. "CATALOG" is reserved and cannot be changed.

**RDS(1 | 2 | 3)**
This is a required keyword. A number in the range of 1-3 to identify the repository data set pair to which the requested DSCHANGE action is to be applied.

1. The primary repository data set pair (COPY1).
2. The secondary repository data set pair (COPY2).
3. The spare repository data set pair (SPARE).

**ACTION(SPARE | DISCARD)**
This keyword is required. The action to be applied to the repository data sets that are specified in the RDS parameter.

**SPARE**
Request to change the repository data set pair disposition to SPARE status. The SPARE action can only be executed against a repository data set pair with DISCARD status. The SPARE repository index data sets (RIDs) and the SPARE repository member data sets (RMDs) must be empty.

**DISCARD**
Request to change the repository data set pair disposition to DISCARD status. The DISCARD action can be executed against either of the active repository data sets (the COPY1 or COPY2) or the SPARE repository data sets. A data set must be set to DISCARD status before a new data set can be defined. The repository must be in a stopped state for this request to process the DISCARD action against COPY1 or COPY2. The repository is not required to be stopped to process the DISCARD against the SPARE.

**LIST command for FRP BATCH**

Use the LIST FRPBATCH command to list information about one IMSRSC repository or all repositories that are defined to the Repository Server (RS) catalog repository data sets.

Subsections:

- “Syntax” on page 481
- “Keywords” on page 481
Syntax

LIST REPOSITORY(repository_name)

STATUS

Keywords

REPOSITORY()
List details for a specific repository that is defined to the RS catalog repository data sets. The name of the repository for which to list information.

STATUS
List the details for all the repositories that are defined to the RS catalog repository data sets.

The following information is returned:
• Name of the repository
• Status of the repository
• Date when the repository was last updated and the user ID of the user who updated it

Related concepts:
- Overview of the IMSRSC repository (System Definition)

Related tasks:

RENAME command for FRP BATCH

Use the RENAME FRP BATCH command to rename an IMSRSC repository.

Subsections:
- “Syntax”
- “Keywords”

Syntax

RENAME REPOSITORY(repository_name) REPOSITORYNEW(repository_new_name)

Keywords

REPOSITORY()
This is a required keyword. The current name of the repository to be renamed. "CATALOG" is reserved for internal use and cannot be renamed.

REPOSITORYNEW()
This is a required keyword. The new name of the repository to be renamed. The name can be up to 44 characters long. Valid characters are A-Z (uppercase only), 0-9, and the following symbols: period (.), underscore (_), number sign (#), dollar sign ($), and at sign (@). All lowercase characters are converted to uppercase.

A repository name of "CATALOG" cannot be used, because it is reserved for Repository Server (RS) usage.

Related concepts:
START command for FRP BATCH

Use the START FRP BATCH command to start an IMSRSC repository.

Subsections:
- "Syntax"
- "Keywords"

Syntax

```
START-REPOSITORY(repository_name) [OPEN(NO | YES)] [MAXWAIT(seconds, CONTINUE | IGNORE | ABORT)]
```

Keywords

REPOSITORY()
This is a required keyword. The name of the repository data set to be started. The Repository Server (RS) catalog repository data sets cannot be started using the START command.

OPEN(NO | YES)
This keyword is optional. Specifies whether to open the repository data sets immediately after the repository is started.

NO Repository data sets are opened when a user first connects to the repository, or immediately if AUTOOPEN=Y is defined for the repository with the ADD FRP BATCH command. This is the default.

YES Repository data sets are allocated and opened when the repository is started.

MAXWAIT(5 | seconds, CONTINUE | IGNORE | ABORT)
This keyword is optional. The maximum number of seconds (0-9999) that the utility waits for the START operation to complete. The default is 5 seconds. A value of 0 means that the utility does not wait and returns a code immediately.

MAXWAIT also specifies the action to take if the START operation is not complete when the MAXWAIT period expires (when the request to the server to start the user repository is successful but the batch utility is not able to confirm that the repository is in the requested state).

CONTINUE
Command processing continues even when the MAXWAIT period expires. The return code is set to 4.
Command processing continues even when the MAXWAIT period expires. No return code is set.

Command processing is terminated when the MAXWAIT period expires. The return code is set to 8.

Related concepts:

Overview of the IMSRSC repository (System Definition)

STOP command for FRP BATCH

Use the STOP FRP BATCH command to stop an IMSRSC repository that is defined to the Repository Server (RS) catalog repository data sets.

Subsections:

- "Syntax"
- "Keywords"

Syntax

```
STOP REPOSITORY(repository_name)

MAXWAIT(seconds, CONTINUE | IGNORE | ABORT)
```

Keywords

REPOSITORY()

This is a required keyword. The name of the repository data set to be stopped. The RS catalog repository data set cannot be stopped using the STOP command.

Requests that the RS stop this repository, preventing further connections to it. If the repository data sets are allocated, the server deallocates the data sets after all write operations are completed and closes the repository.

MAXWAIT(seconds, CONTINUE | IGNORE | ABORT)

This keyword is optional. The maximum time (0-9999) in seconds that the utility waits for the STOP operation to be completed. The default is 5 seconds. A value of 0 means that the utility does not wait and returns a code immediately. MAXWAIT also specifies the action to be taken if the STOP operation has not been completed when the MAXWAIT period expires (when the request to the server to stop the user repository is successful but the batch utility is not able to confirm that the repository is in the requested state).

CONTINUE

Command processing continues even when the MAXWAIT period expires. The return code is set to 4.

IGNORE

Command processing continues even when the MAXWAIT period expires. No return code is set.
Command processing is terminated when the MAXWAIT period expires.
The return code is set to 8.

Related concepts:

**UPDATE command for FRPBATCH**

Use the UPDATE FRPBATCH command to update an IMSRSC repository
definition in the Repository Server (RS) catalog repository data sets. Use this
cmd to change the IMSRSC repository data sets or the AUTOOPEN
specification of a repository.

Subsections:
- “Syntax”
- “Keywords”

**Syntax**

```
UPDATE REPOSITORY(repository_name)

REPDSN1RID(ds1_rid_dsname) REPDSN1RMD(ds1_rmd_dsname)
REPDSN2RID(ds2_rid_dsname) REPDSN2RMD(ds2_rmd_dsname)
REPDSN3RID(ds3_rid_dsname) REPDSN3RMD(ds3_rmd_dsname)
AUTOOPEN(YES) AUTOOPEN(NO)
SECURITYCLASS(NULL) SECURITYCLASS(securityclassname)
```

**Keywords**

**REPOSITORY()**
This is a required keyword. The name of the repository to be updated.
“CATALOG” is reserved and cannot be updated.

**REPDSN1RID()**
This is an optional keyword. The name of the primary repository index data set (RID). If this parameter is omitted, or if NULL is specified, the data set is
not updated.

If you specify REPDSN1RMD, but do not want to update this parameter, you
still must specify this parameter (with NULL).
REPDNS1RMD()
This is an optional keyword. The name of the primary repository member data set (RMD). If this parameter is omitted, or if NULL is specified, the data set is not updated.

If you specify REPDNS1RID(), but do not want to update this parameter, you still must specify this parameter (with NULL).

REPDNS2RID()
This is an optional keyword. The name of the secondary RID. If this parameter is omitted, or if NULL is specified, the data set is not updated.

If you specify REPDNS2RMD(), but do not want to update this parameter, you still must specify this parameter (with NULL).

REPDNS2RMD()
This is an optional keyword. The name of the secondary RMD. If this parameter is omitted, or if NULL is specified, the data set is not updated.

If you specify REPDNS2RID(), but do not want to update this parameter, you still must specify this parameter (with NULL).

REPDNS3RID()
This keyword is optional. The name of the spare RID. If this parameter is omitted, or if NULL is specified, the data set is not updated.

If you specify REPDNS3RMD(), but do not want to update this parameter, you still must specify this parameter (with NULL).

REPDNS3RMD()
This keyword is optional. The name of the spare RMD. If this parameter is omitted, or if NULL is specified, the data set is not updated.

If you specify REPDNS3RID(), but do not want to update this parameter, you still must specify this parameter (with NULL).

AUTOOPEN(YES | NO)
This keyword is optional. Specifies when repository data sets are allocated.

YES
Repository data sets are allocated when the repository is started. This is the default.

NO
Repository data sets are allocated when you first connect to the repository.

SECURITYCLASS(NULL | securityclassname)
This keyword is optional. Specifies the name of the security class to be used for the user repository. The name must be left-aligned, an 8-byte name with trailing contiguous spaces. The first character must be alphabetic and subsequent name characters alphanumeric.

If this parameter is omitted, or if NULL is specified, there is no security for this user repository. The name specified can be the same name as the SECURITYCLASS specified for the RS address space in the FRPCFG member of the IMS PROCLIB data set.

Part 7. VTAM and SNA reference information

The topics in this section provide reference information about VTAM and SNA.
Chapter 36. Bind parameters for SLU P and LU 6.1

You can search these topics for the session parameters that IMS specifies when establishing connection using the VTAM OPNDST macro instruction. These parameters define the rules that a logical unit must follow when communicating with IMS.

Restriction: A VTAM restriction exists on the OUTBUF and RECANY buffer sizes for logical units requiring a bind from IMS.

The following outbound (from IMS to the SLU) BIND formats apply to the device types indicated in the following topics.

Related reference:
Chapter 38, “Format for CINIT user data parameters,” on page 507

Finance communication system bind parameters

You can use this table to search for the session parameters that are defined as UNITYPE=FINANCE or UNITYPE=SLUTYPEP on the TYPE macro or an Extended Terminal Option (ETO) logon descriptor for a Finance Communication System.

<td></td>
<td></td>
<td>BIND FORMA</td>
</tr>
</tbody>
</table>

Notes:

1. Bytes 1 through 7, 10, and 11 are set to the indicated values set by IMS and cannot be changed by the user. The pacing parameter is defined in the VTAM list LU definition or through the mode table entry for the LU (VTAM DLOGMOD parameter).
2. Bytes 0, 9, and 27 through 35 are set by VTAM.
3. The receive-any buffer size is determined by the user-supplied value for size on the RECANy keyword parameter of the COMM macro statement, less 28 bytes.
4. IMS does not set the buffer size for the 4701/4702.
5. When the BIND data issued is an XRF system that uses the USERVAR instead of MNPS, the following structured user segment is included:
   - Length of USERVAR segment - X'09'
   - USERVAR segment indicator - X'03'
   - USERVAR (8 bytes) - USERVAR of the XRF system

- z/OS: Request unit (RU) formats

IMS as primary half session

A specific bind format is sent by IMS during an IMS-to-other session initiation. If the mode table entry indicates negotiated bind, IMS overrides the mode table primary NAU protocol field with the indicated values prior to sending the bind.

IMS allows some parameters to be optionally set by a VTAM mode table entry or negotiated bind response. IMS then operates within the indicated constraints. For a non-negotiated bind, IMS checks the parameters for validity before sending the bind. For negotiated bind, IMS checks the parameters for validity prior to sending the BIND request and upon receipt of the bind response, because the secondary half session can modify parameters within the constraints indicated in the following table.

<th>Content</th>
<th>BIND FORMAT description¹</th>
</tr>
</thead>
</table>

Notes:

1. The length of the BIND RU cannot exceed 256 bytes; otherwise, a negative response is returned.

2. Set to indicate possible in-bracket or process restart. Set by IMS on bind when response mode output remains on the queue or when IMS is in conversational mode. Can also be sent on a negotiated bind response by the other half session.

3. The receive-any buffer size is determined by the user-supplied value for size on the RECANY keyword parameter of the COMM macro statement, less 28 bytes.

4. When the bind indicates that the other half session does not support the SCHEDULER process, IMS sends all unsolicited and asynchronous output using ATTACH.

5. Unstructured user data is ignored and not provided by IMS.

6. Structured user data formats. A structured field contains architected or subsystem-defined information and provides a means for subsystems to communicate data. Each structured field contains a field identifier (subfield number) and length. A structured data field can contain unstructured data.

   If structured field (M+3-N) is X'00', it contains unstructured data as follows:

   1  Length of unstructured data field (including subfield key field). If zero, this field can be omitted entirely.

   2  Subfield key: X'00'

   3-N  Unstructured data. If the structured subfield number is X'03', an 8-byte USERRVAR name follows the subfield.

   If the structured field (M+3-N) is X'01', it contains a session qualifier as follows:

   1  Length of session qualifier field (including subfield key field). If zero, this field can be omitted entirely.

   2  Subfield key: X'01'

   3  Length of primary resource qualifier (X'00' means no primary source qualifier is present). Values 0 to 8 are valid.

   4-N  Primary resource qualifier

   N+1  Length of secondary resource qualifier (X'00' means no secondary resource qualifier is present). Values 0 to 8 are valid.

   N+2-M  Secondary resource qualifier

   M+1  Length of password (X'00' means no password is present). Values 0 to 8 are valid.

   M+2-P  Password. Ignored on bind or bind reply from IMS and is not sent on bind or bind reply. IMS indexes structured fields to find field X'01', a session-qualifier field, when these parameters are required for session initiation using parallel sessions.

   M+3-N  If the structured field has a subfield of X'02', IMS interprets the field as an MSC partner ID. If bind is issued in an XRF environment that uses USERRVAR instead of MNPS, an additional structured segment is included in the user data. The format of this segment is:

   1  Length of USERRVAR segment, X'09'

   2  Subfield key, X'03'

   3-10  8-byte field containing USERRVAR of the XRF complex

7. The URC and secondary LU name are not used by IMS but are shown for compatibility purposes.
IMS as secondary half session

A specific bind format can be received by IMS during an IMS-to-other session initiation. If the bind parameters that are received indicate a negotiated BIND request, IMS overrides the secondary NAU protocol field with the indicated values before sending the bind response.

IMS allows some parameters to be optionally set using the bind and operates within the indicated constraints.

Chapter 37. Bind parameters for SLU 1 and SLU 2

IMS specifies different session parameters when establishing connection with SLU 1 and SLU 2. These parameters define the rules that a logical unit must follow when communicating with IMS.

The following outbound (from IMS to the SLU) BIND formats apply to the device types indicated in this section.

Notes:

1. Bytes 0-6, 9, and 10 are set to the indicated values by IMS and cannot be changed by the user.

2. Byte 8 and bytes 26 through 34 are set by VTAM. You should set the remaining bytes to 0 (zero), but it is not mandatory.
Chapter 38. Format for CINIT user data parameters

This topic describes the CINIT user data parameters and the syntax rules for them.

For all non-MSC VTAM terminal types, IMS can receive user data parameters from the following sources:
- IMS (/OPNDST command)
- IMS autologon request
- User logon (such as SNA INITSELF command)
- Installation Logon exit routine (DFSLGNX0)
- Signon exit routine (DFSSGNX0)
- Destination Creation exit routine (DFSINSX0)

User data parameters are optional for migration purposes. However, when a match must be made between the terminal and user for session initiation, user data parameters are required for:
- ISC parallel session (LU 6.1 architecture)
- Finance (3601) and SLU P terminals, when used with ETO

All parameters, optional and required, appear in the CINIT user data field and are available to IMS when the VTAM Logon exit routine is scheduled.

During logon and signon processing, IMS performs minimal processing on CINIT user data parameters before calling the Installation Logon exit routine (DFSLGNX0) and the Signon exit routine (DFSSGNX0). If the Logon or Signon exit routines are not supplied, IMS assumes a default user data format.

**User data format**

The format for the CINIT user data is shown in the following syntax diagram.

```
LOGOND=Iname userid=
```

For these parameters, blanks are required and are the only recognized delimiters.

Do not use more than one blank to delimit parameters.

**Parameters**

**LOGOND=Iname**

Specifies logon descriptor name to be used for the terminal attempting to log on to IMS. *Iname* is one to eight bytes in length. The LOGOND and USERD parameters are valid only for Extended Terminal Operation (ETO).

**userid**

Specifies the 1- to 8-byte user ID of the user logging on to IMS. The *userid* parameter indicates that the user associated with this ID will also sign on to IMS.
The *userid* parameter is required for Finance, SLU P, ISC, and output-only devices (such as printers).

**Restriction:** ISC is restricted to only the user ID that translates to the ISC SUBPOOL name (SNA PHS/SHS qualifier). For ISC parallel sessions, the DFSLGNX0 exit routine receives only the user ID that translates to the ISC subpool name (SNA PHA/SHA qualifier).

**USERD=uname**

Specifies the 1- to 8-byte user descriptor name to be used to create the user control block structure at signon.

**userdata**

Specifies additional data for the Signon exit routine (DFSSGNX0) or the Sign On/Off Security exit routine (DFSCSGN0) and security products, such as RACF. For the exit routines, your installation defines the format of the *userdata* fields.

For RACF, the format of the *userdata* is:

**userpw**

Identifies the 1- to 8-byte user password that is associated with the previously entered *userid*. No keyword precedes the user password.

**GROUP groupname**

Identifies groupname as the 1- to 8-byte group name that is associated with the *userid* parameter. The GROUP keyword and associated parameter are optional.

**NEWPW nuserpw**

Identifies *nuserpw* as a new user password that replaces the current password, *userpw*.

The ETO logon descriptor name, *lname*, applies to IMS logon processing. All remaining optional parameters, however supplied, are passed to ETO user allocation, signon processing, and the security product, such as RACF. If a security product is used, all parameters not applicable to that product must be deleted before it is called. The parameters can be deleted in the DFSLGNX0, DFSSGNX0, and DFSCSGN0 exit routines.

Chapter 39. SNA character string controls

SNA character string controls (SCS) describe specific functions for the EBCDIC control codes. You can use the primary functions that are described to format a printed page or an alphanumeric display screen.

Functions are also defined for codes that set modes of device operation, define data to be used in a unique fashion, or are used for communication between a device operator and an application program (where the specific function associated with the code is defined in a protocol established between a program and an operator).

An SCS data stream consists of a sequential string of control and data characters. Control function characters in the form of SCS-defined control codes can be intermixed with graphic data characters. Other data types (such as binary and packed decimal) are permitted only in conjunction with the transparent (TRN) control.

SCS control codes appear within the data portion of the request unit (RU). A function management (FM) header can precede SCS data within an RU. Functions such as component selection are performed by FM header functions and are not included as SCS functions.

SCS functions do not include data flow control functions, even when these functions are available to a keyboard operator through keys on the keyboard. For example, CANCEL is a data flow control request that can be initiated by a key on the keyboard.

Format controls

Formatting control functions format the output media at the device on a line and page basis. In addition to these controls, a device using SCS also automatically formats the character string to fit the line length of the device.

Automatic new line generation eliminates device line length dependencies from those applications in which a specific output format is not required. Therefore, the same character string is sent to devices with varying line length capabilities without the requirement to reformat the character string.

Where specific line and page formats are required, the formatting control functions are used. The automatic new line feature is always active; however, a character string formatted for a given line length can be presented on a device with a shorter line length without loss of data, but the format is lost. When the situation is reversed, where a character string constructed for a maximum presentation position is less than the line length of the device to which it is directed, use of the smaller maximum presentation position allows the string to be presented without loss of format.
Control function code assignments

You can search this table for SCS control functions that are assigned to EBCDIC codes.

Table 110. Control function code assignments.

</tr>
</tbody>
</table>

Note:
1. Functions with parameters

Parameters in SCS can be one of two types:
   • Function parameters extend the function defined by the function code. For example, the PP control function has a function parameter to explicitly define the positioning function performed. The form for a function parameter is a single EBCDIC character.
   • Value parameters specify a numeric value for the function. For example, the PP function also has a value parameter for it. If the move is relative to the current position, the value parameter specifies the number of columns or lines the presentation position is to be moved from its current position. If the move is absolute, the value parameter specifies the absolute column or line number to which the presentation position is to move. The form for a value parameter is a 1-byte binary number.
